The chemical determination of fecal matter in water. W. AUSTEN. *Wasser u. Gas* 15, 484-92(1925).—A no. of tests on various waters indicate Jolles' method for the detn. of urine in water, to be uniformly successful. The method used is as follows: Add 1 cc. of a 5% alc. soln. of thymol to 10 cc. of the water to be tested. Shake, add 10 cc. of fuming HCl (sp. gr. 1.19) contg. 5 g. Fe chloride per l. Allow to stand 5 min., add 4 cc. of CHCl_3 and shake again. The presence of a violet color indicates the presence of urine in the water. A. found the reaction was not hindered by Cl, or NO_3 , but was hindered by NO_2 . This is overcome by the addn. of Mohr's salt. This test also cannot be used on filtered water, filtering removing the indican, the substance in urine upon which this test is based. This test is sensitive in a diln. of 1:100. A modification of Winkler's method for protein NH_3 is also given. MARTIN E. FLENTJE

Importance of differentiating the colon-aerogenes group in examining water. J. J. HINMAN, JR. *Am. J. Public Health* 15, 614-9(1925).—The detection of the colon-aerogenes group is a most important part of water lab. procedure. In well supplies or supplies supposed to be free from surface wash, the presence of any lactose fermenter, even a spore former, is objectionable. In purified surface waters the presence of the members of the colon-aerogenes group is permissible to the limit of the Treasury Dept. standards, unless those present belong to the coli section of the group in which case an adverse report should be given. EDWARD BARTOW

Studies on water purification. I. Adsorption of acids and alkalies by Kambara earth. SHU OIKAWA. *J. Biochem. (Japan)* 5, 49-55(1925).—Adsorption of acids and alkali from solns. is affected most within the first 5 min. of shaking with the Kambara earth. Further shaking has practically no influence. It is very probable that its adsorbing power depends upon the presence of colloidal silicic acid and of humus colloids. S. MORGULIS

Modern British practice in water softening. III. Lime cream and soda ash plants. D. BROWNLEE. *Ind. Chemist* 1, 386-92(1925); cf. *C. A.* 19, 2858. E. J. C.

The prevention of boiler scale formation in steam boilers. HELLMERS Z. *angew. Chem.* 38, 609-10(1925).—Pptn. of boiler scale from both temporary and permanent hardness is lessened by a 0.1% tannin soln. The ppt. formed with tannin present can be redissolved by excessive washing, and is in a soft, loose form. C. G. K.

Feed water purification. J. NEIDE. *Gesundh. Ing.* 47, 570-1(1924).—Carbonate scale, because of its porosity, is a poorer heat conductor than sulfate scale, with its cryst. structure. Complete pptn. of the carbonates, rather than of the sulfate, should be aimed at in feed water purification. Dissolved gases, especially O_2 , cause corrosion and blisters and should be removed. MARTIN E. FLENTJE

Coagulation processes during the purification of river water. C. P. MOM. *Mededel. Burgerlijken Geneeskund. Nederland-Indie* Part 1, 27-71(1925).—This is a detailed study of the occurrence and compn. of colloidal clay in the water of the Tjiliwong River and the coagulation of this clay by means of $\text{Al}_2(\text{SO}_4)_3$. A dose of 15 mg. of $\text{Al}_2(\text{SO}_4)_3$ per l. of river water was sufficient to cause coagulation, and the most favorable reaction was about p_{H} 5.5 to 6.0. The colloidal Al_2O_3 is the coagulative factor proper, the H and Al ions supporting the process. The Al_2O_3 has but a weak discharging power, and its effect has to be ascribed to its strong flocculating or coalescing power. G. F. R.

The iron removal plant of Löbau. F. H. SCHILLING. *Der Strassenbau* 11, 91-3(1924); *Gesundh. Ing.* 47, 352(1924).—A description of the Fe removal plant of Löbau. MARTIN E. FLENTJE

Color and other phenomena of water from an unstripped reservoir in New England. C. M. SAVILLE. *J. New Eng. Waterworks Assoc.* 39, 145-70(1925).—A rather complete report on the variation in color for several years in the water of the several reservoirs which make up the Hartford (Conn.) supply. In a new unstripped reservoir the color of the water will be greater in the reservoir than that of the inflowing streams. After a period of 3-10 years the color of the water will be less than that of the inflowing water. A discussion of the paper by other experts accompanies the article. R. E. G.

Influence of curvature on air saturation of water and its relation to the air-binding of filters. J. R. BAYLIS. *Ind. Eng. Chem.* 17, 974-9(1925).—The soly. of air, and probably of other gases, varies with the curvature of the gas-water surface. Concave surfaces increase and convex surfaces apparently decrease the satn. point. A much greater concn. of dissolved air is necessary to start bubble formation against solid surfaces than is necessary to cause very small bubbles to increase in size. The release of air in filter beds is always started by air being carried into the bed, or by air not driven out in washing. J. M. HOLDERBY

Water treatment on the Island of Jersey. WILFRED RUSHTON. *Surveyor* 66, 467-8, 513-4(1924); cf. *C. A.* 19, 1171.—Treatment of reservoir by Cu sulfate applied with a sprayer successfully killed undesirable algae without affecting fish life. Rearing of fish in filter beds is advocated. R. E. GREENFIELD

Iron deposit in cast iron pipe. J. R. FOX. *Surveyor* 66, 465-6, 491-2, 509-10 (1924); cf. *C. A.* 19, 1171.—Use of lime, sodium silicate, scraping, etc., to prevent "furring" of pipes by iron bacteria is discussed. The best remedy is considered to be iron removal. The paper is discussed by other experts. R. E. GREENFIELD

Municipal water supply problems of Atlanta, Georgia. P. H. NORCROSS. *Proc. Am. Soc. Civil Eng.* 51, 969-98(1925).—Water from the Chattahoochee River is pumped into settling basins, is treated with alum and lime, resettled and filtered on gravity filters. The new water-works are described. J. M. HOLDERBY

The injuriousness of *Dreissensia polymorpha* Pallas to water plants. F. ROCH. *Gesundh. Ing.* 48, 97-8(1925).—R. describes the mussel *Dreissensia polymorpha* Pallas, and the danger of its presence to water plants. Chlorination is probably the best means of eradication. A bibliography is given. MARTIN E. FLENTJE

Filtration for swimming baths. ANON. *J. Roy. San. Inst.* 46, 47-52(1925).—Filtration of "swimming bath" water results in clearer water and in a saving in fuel, water cost, attendants, wages, etc. R. E. GREENFIELD

The protection of underground water supplies. A. B. CATHCART. *Surveyor* 66, 5-6(1924).—A discussion of lack of legal remedies in pollution of underground water supplies. R. E. GREENFIELD

Modern methods of sewage purification; precipitation and filtration. THOMAS CALBERT. *Surveyor* 68, 219-20(1925).—A description of the settling tanks and sewage-handling devices used in the sewage disposal plant of Howich (Scotland). R. E. G.

Control of odors from sewage-treatment plants. J. F. SKINNER. *Proc. Am. Soc. Civil Eng.* 51, 1182-92(1925); cf. *C. A.* 19, 2097.—A discussion. J. M. H.

The Hoffmann system of sewage purification. KEPNER. *Gesundh. Ing.* 47, 590(1924).—A sepn. of solid and fluid matter is effected by means of a spiral, opening into a constricted conduit. A sludge, usable as fertilizer, is obtained. M. E. F.

Memorandum regarding the utilization of sea water as the transportation medium in a sewerage installation. A. GORDON GUTTERIDGE. *J. Roy. San. Inst.* 46, 42-6 (1925).—Where sea water is used for sewage transportation the following difficulties, none unsurmountable, are encountered: (1) increased corrosion of metal fixtures, (2) decreased carrying power due either to greater penetration of the solids or the result of chem. action making the solids settle more readily, (3) greater pptn. of grease or other substance causing clogging of sewers, decreased biological activity in purification processes. R. E. GREENFIELD

Two-story vs. separated sewage purification tanks. IMHOFF. *Techn. Gemeindeblatt* No. 13, 151-5(1924); *Gesundh. Ing.* 47, 582(1924).—I. discusses the relative merits of the 2 compartment and sepd. settling and digestion tanks. M. E. F.

Factors influencing the bacterial flora of an Imhoff tank. MARGARET HOTCHKISS. *Am. J. Pub. Health* 15, 702-4(1925); cf. *C. A.* 19, 552.—A study of the growth curves for different groups of bacteria suggests that the predominance of any group may depend upon the phase of digestion within the tanks. Variations in the manner in which the tanks are operated influence the general bacterial flora, and tend to obscure any possible seasonal variation. J. M. HOLDERBY

The activated sludge system of sewage purification. O. KAMMANN. *Techn. Gemeindeblatt* No. 1-2, 13-6(1924); *Gesundh. Ing.* 47, 353(1924).—A review of Am and English experiences with activated sludge. MARTIN E. FLENTJE

Sewage purification by means of activated sludge. IMHOFF. *Techn. Gemeindeblatt* No. 11-12, 132-6(1924); *Gesundh. Ing.* 47, 582(1924).—A review of sewage purification by means of activated sludge in U. S. and England. M. E. F.

The activated sludge process. ANON. *Surveyor* 66, 24-31, 59-61(1924).—Report of papers and discussions presented at the International Conference of Sanitary Engineering. R. E. GREENFIELD

Elasticity of activated sludge process. JOSHUA BOLTON. *Surveyor* 66, 85-6 (1924); cf. *C. A.* 19, 2252.—Very successful purification by means of a "simplex" aerator was obtained even when the practice of shutting off part of the aerators at night was adopted. R. E. GREENFIELD

Purification of cesspool sewage. ANON. *Surveyor* 66, 78(1924).—Septic sewage from cesspools is successfully purified without odor by coarse screening, aeration by means of a special atomizer followed by sedimentation. The sludge is disposed of by digestion and clinker filtration. R. E. GREENFIELD

Sewage purification at Manchester. ANON. *Surveyor* 66, 343-4(1924).—Report on exptl plant with chemical analysis. R. E. GREENFIELD

Elimination of odors from garbage disposal works. S. A. GREELEY. *Proc. Am. Soc. Civil Eng.* 51, 1177-81(1925); cf. *C. A.* 19, 2097.—A discussion. J. M. H.

Mites and occupational disease. A. G. G. THOMPSON. *J. State Med.* 33, 419 (1925).—A discussion of mites and the itches caused by them, especially those connected with the handling of grains, vanilla, copra and transmission from other animals. JACK J. HINMAN, JR.

The spread of dysentery considered from the aspect of public health. PHILIP MANSON-BAHR. *J. State Med.* 33, 401-14(1925).—Flies, water and carriers are considered as vectors of infection. Emphasis is placed on carriers in case of bacillary dysentery and on water in case of amebic dysentery. JACK J. HINMAN, JR.

Shop and factory hygiene. GEORG. WOLFF. *Chem.-Ztg.* 49, 745-7(1925).—An essay outlining the advantages of modern factory control in matters of hygiene, workmen's disability compensation, insurance, state inspection, disposal of waste, smoke abatement, sanitary disposal of gaseous and liquid matter, fire protection, lighting, heating, ventilation, wash rooms and toilets. W. C. EBAUGH

Stream pollution by wastes from by-product coke ovens (LEITCH) 21. **Experimental sprinkling of farm land with Dresden sewage** (FLECK, HEILMANN) 15. **Action of water upon Cu pipes** (TAKESH) 9.

FRANCÉ, R. H.: *Wege zur Natur. Eine Einführung in die Untersuchung der Kleinwelt des Wassers und des Bodens.* (Handbücher für die praktische naturwissenschaftliche Arbeit. Band IV.) Stuttgart: Franckhsche Verlagsbuchhandlung. 47 pp. Reviewed in *Gesundh. Ing.* 47, 548(1924).

Purifying water, etc. K. MORAWE. *Brit.* 231,456, March 25, 1924. In treating H₂O or other liquids by the base-exchange process, the exchange operation is interrupted before the exchange substance is exhausted or the regeneration operation is interrupted before the material is completely regenerated.

Softening water. A. R. BURNETTE. U. S. 1,553,067, Sept. 8. The water is first delivered to a conduit at high pressure, taken from the conduit and heated to the b. p. under that pressure, filtered while still under high pressure and then passed in heat-interchange with water flowing to the app. for softening treatment.

Apparatus for softening water with zeolitic material. W. J. HUGHES. *Brit.* 231,818, April 4, 1924.

Apparatus for softening water with zeolitic material. C. H. NORDELL. *Brit.* 231,817, April 4, 1924.

Deaerating water by successive vacuum treatments. G. H. GIBSON. U. S. 1,556,098, Oct. 6.

Driving air from water by use of carbon dioxide. T. HILL. *Brit.* 231,576, Jan. 1, 1924.

Water-filtering plant. L. RYAN. U. S. 1,554,129, Sept. 15.

Hydrocyanic acid for fumigation. CHEMISCHE FABRIK H. STOLTZENBERG. *Brit.* 231,497, March 27, 1924. HCN for destroying vermin is liberated by the action of H₂O on FeCl₃·2HCN, AlCl₃·2HCN or other similar double compds. of anhyd. HCN with chlorides such as those of Sn and Ti.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

Soils of Brazos, Camp, Ellis, and Washington counties. G. S. FRAPS. Texas Agr. Expt. Sta., *Bull.* 316, 88 pp.(1924). J. J. SKINNER

The solid acidity of the soil. A. DE DOMINICIS AND S. DOJMI. *Ann. chim. applicata* 15, 183-206(1925); cf. *C. A.* 19, 2542.—Systematic expts. were carried out on a no. of soils in the attempt to explain more fully the acidity of soil. Of the soils tested, only one was acid to litmus and none liberated HOAc from Ca(OAc)₂, even after washing with H₂O. To remove bases and carbonates the soils were extd. with dil. HCl, washed, dried at 105-10° and calcined, as a result of which all samples gave an acid reaction with litmus. They were then treated with Ca(OAc)₂ soln. and the free HOAc in the filtrate detd. Dil. HCl dissolved not only carbonates but also certain bases

in the soil, after which treatment the soils rendered salt solns. acid by reappropriating their basic constituents (cations). The action of the HCl was the same regardless of its concn. Provided that it is deficient in Ca compds. a soil can thus become acid through the fixation of the cation of an electrolyte. The addn. of CaCO_3 to soils exhd. with HCl and then treated with Ca(OAc)_2 and washed inhibited the dissociation and removal of bases on subsequent prolonged washing with H_2O . The expts. indicate that there are 2 types of basic constituents in soils, *mobile bases* and *fixed bases*. *Mobile bases* for the greater part are bound to colloids in the soil on which they are adsorbed in amts. which vary continuously, the force of this adsorption differing from ordinary chem. affinity. *Fixed bases* comprise the basic component of the mols. of the cryst. and colloidal compds. of the soil, are present in const. and definite proportions and cannot be sepd. without profound chem. and structural alteration of the soil. When added to a soil in which the mobile bases are deficient or absent, Ca compds. do not improve the condition of the soil by neutralizing its acidity but improve it by virtue of their power as electrolytes of coagulating the colloids from their state of dispersion and rendering them immobile and incapable of being washed away. A crit. review and discussion of past exptl. and theoretical work on the acidity of the soil are included, with 44 references.

C. C. DAVIS

Investigation of soil acidity by means of plant experiments. H. KAPPEN. *Z. Pflanzenernahr. Dungung* **4A**, 202-11 (1925).—The height of alfalfa plants was inversely correlated to a high degree with the amt. of hydrolytic acidity found in the soil. Barley, turnips, clover beans, alfalfa and mustard are more sensitive to exchange acidity than oats, corn, rye, and potatoes. Physiologically alk. fertilizers are more beneficial to the latter group of crops than to the preceding. Superphosphate does not increase the exchange acidity of the soil to which it is applied. Its use in large quantity prevents $(\text{NH}_4)_2\text{SO}_4$ rendering the soil acid.

A. L. MEHRING

Soil acidity and its determination. B. TACKE. *Z. Pflanzenernahr. Dungung* **4A**, 215-6 (1925). The author's method for detg. soil acidity gave results not always in agreement with those obtained with Daikuhara's method.

A. L. MEHRING

Soil acidity and its determination. E. RAMANN. *Z. Pflanzenernahr. Dungung* **4A**, 217-21 (1925). The relation of acid permutites to acid soils is discussed.

A. L. M.

Base exchange in relation to the swelling of soil colloids. E. A. FISHER. *Trans. Faraday Soc.* **20**, 603-4 (1925). There is evidence that this problem might be profitably investigated in the light of the Donnan theory.

P. R. DAWSON

Base exchange in relation to adsorption. E. A. FISHER. *Trans. Faraday Soc.* **20**, 599-602 (1925). A discussion and argument for a chem. explanation of many so-called "adsorption" phenomena.

P. R. DAWSON

Considerations on some elements of the fertility of the soil in Ticino (Tessin) Canton. A. VERDA. *Helv. Chim. Acta* **8**, 412-38 (1925).—From an agricultural viewpoint the canton is divided into (1) the plain of Magadino, (2) the delta of the Maggia, (3) the plain of Veduggio, (4) the delta of Cassarate, (5) the Scairolo plain, and (6) the Mendrisio district. Numerous chem. analyses of the surface and subsoil waters and of the rocks and many mechanical and chem. analyses of the soils of these regions are given.

ALBERT R. MERZ

Chemical analysis and fertility of West Virginia soils. A. C. BRYAN and E. P. DEATRICK. West Virginia Agr. Expt. Sta., *Bull.* **184**, 27 pp. (1924).—The chem. analysis of 485 soils representing the important soil series of the State are reprinted. Soils derived from sandstone and shales have lower N and P content than those derived from limestone, and are more acid and less fertile. All the soils contained an av. of 1% of K. The sandstone and shale soils respond to treatments of P, N and lime.

J. J. S.

The experimental sprinkling of farm land with Dresden sewage. FLECK and HEILMANN. *Gesundh. Ing.* **48**, 6-8 (1925).—Farm land which has been sprinkled with filtered Dresden sewage produces, at a profit, considerably greater crops than land not so treated. These expts. are to be enlarged and contd.

M. E. F.

Soil bacteriological studies. M. DÜGGELI. *Landw. Jahrb. Schweiz.* **38**, 203-51 (1924); *Expt. Sta. Record* **52**, 720.—A summary is given of the results of a large no. of studies begun in 1908 on the activities of soil organisms, particularly N-fixing organisms, in certain Swiss soils under different methods of fertility treatment. The results showed that soils fertilized with potash and P_2O_5 , but not with N, contained a much greater no. of nonsymbiotic N-fixing organisms of aerobic types, such as *Azotobacter chroococcum*, and of anaerobic types, such as *Bacillus amylobacter*, than soils fertilized with NaNO_3 . The latter soils contained the greater no. of denitrifying organisms. Plowing these soils and treating them with liquid cow manure or stable manure increased the nos. of *A. chroococcum*, but plowing seemed to be somewhat injurious to the *B. amylobacter*.

A marked decrease in bacterial nos. in these soils was noted during the period from April to July. This was found to be due not only to a decrease in the amt. of available moisture and easily assimilable org. matter, but also to the rapid multiplication of soil protozoa, which was favored by the higher soil temps. In fact, the destruction of bacteria by protozoa during this period is considered to be the greatest cause of their rapid decrease in nos. H. G.

Behavior of bacteria, especially soil bacteria, toward carbon disulfide and the influence of treating soils with carbon disulfide on plant growth. A. MAASSEN AND H. BEHN. *Arb. Biol. Reichs. Land-Forstw.* **12**, 285-338(1924); *Expt. Sta. Record* **52**, 721.—Liquid CS_2 reduced markedly the no. of bacteria in soils, being the most destructive to the nitrifying bacteria and the least to the denitrifying and putrefactive bacteria. It was as destructive to soil bacteria when dissolved in water as when in vapor form. The vapor form was more destructive to *Azotobacter* than water half satd. with CS_2 , but less so than fully satd. water. Further expts. showed that the treatment of ordinary soils in the field with CS_2 generally favored plant growth. This favorable influence was usually also observed in pot expts. However, soil which had shown increases in yield due to such treatment in the field did not so react when potted. No increase in crop yield resulted from the treatment of sterilized soil with CS_2 . There was usually a residual effect of CS_2 treatment in field soils, which was noticeable in the second crop, but no such residual effect was observed in pots. The favorable action of CS_2 on the yield of crops and its residual effect were considerably weakened by the addn. of org. nitrogenous material, such as bone meal, manure, or moor soil. This was especially true with manure when added some time before the CS_2 treatment and indicates that the favorable influence of CS_2 is not due to an increase in the availability of nitrogenous org. matter. The yields of crops in soils well supplied with sol. plant nutrients were usually increased by CS_2 treatment, although this effect was not observed in sterilized soils aside from a small increase in yield in sterilized but fertilized sand. This indicates that CS_2 exercises a growth-promoting action on crops. However, it is concluded that the favorable residual effect of this substance cannot be explained in this manner, but may be due to chem. or biological changes produced. It is also considered possible that the favorable influence of treatment with CS_2 is due to partial sterilization of the soil, whereby injurious organisms are killed and organisms tending to increase the supply of available plant nutrients are permitted to multiply in greatly increased nos. H. G.

Phosphoric acid as an industrial chemical reagent. J. W. TURRENTINE. *Chem. Met. Eng.* **32**, 291(1925).—"Emphasis should be placed on the potential value of H_3PO_4 to agriculture through its use as an industrial chem. reagent as a possible substitute for H_2SO_4 and other acids in those applications where sol. phosphates useful for fertilizer may be yielded as a by-product." E. J. C.

Two new calcareous fertilizers, "Fosfaragonite" and "Carbide Italia." ANON. *Giorn. Riscicoltura* **15**, 120-3(1925).—"Fosfaragonite" analyzed 2.10% H_2O , 39.21 CO_2 , 1.01 P_2O_5 and 4.48 total SiO_2 . "Carbide Italia" contained 9.00% H_2O , 30.14 CO_2 and 2.00 total SiO_2 . ALBERT. R. MERZ

Carbon dioxide fertilizer GERLACH AND SEIDEL. *Z. Pflanzenernähr. Düngung* **4B**, 241-7(1925).—A material consisting mainly of finely ground peat, wood charcoal and pyrolusite is said to liberate CO_2 in the soil by catalytic oxidation. This material injured lupines when applied to them. A. L. MEHRING

Action of silica in increasing the yield (of plants). O. LEMMERMANN, H. WIESSMANN AND K. SAMMET. *Z. Pflanzenernähr. Düngung* **4A**, 265-315(1925).—"When SiO_2 is deficient, SiO_2 greatly increases the yield of dry matter and grain of various crops in sand culture. The exptl. results are presented in 25 tables. The results indicate that SiO_2 cannot replace P_2O_5 in the metabolism of the plant nor make up the total mineral constituents necessary but not satisfied by P_2O_5 . The increases are believed to be due to the presence of SiO_2 , rendering the P_2O_5 more available to the plant. A. L. MEHRING

Action of silica in increasing the yield (of plants) in sand cultures with insufficient phosphoric acid. FR. DUCHON. *Z. Pflanzenernähr. Düngung* **4A**, 316-25(1925).—"The increased yield obtained by Lemmermann and his colleagues in sand cultures deficient in P_2O_5 by adding colloidal SiO_2 is believed to be due to the improvement of the physical condition of the soil. Other colloidal materials or green manure added to sand also reduce the amt. of phosphatic fertilizers needed. In natural soils contg. sufficient colloidal material the addition of SiO_2 has no effect. A. L. MEHRING

Remarks on the article by Fr. Duchon. O. LEMMERMANN. *Z. Pflanzenernähr. Düngung* **4A**, 326-30(1925).—In reply to Duchon (preceding abstract) it is claimed

that colloidal SiO_2 does not affect the absorption of N and K_2O by plants as it does P_2O_5 . Furthermore, the effect of SiO_2 was observed in sand cultures to which humus was added.

Physiological character of ammonium nitrate (towards plants). D. N. PRIANISCHNIKOW. *Z. Pflanzenernähr. Düngung*, **4A**, 242-50 (1925).— NH_4NO_3 is usually physiologically acid. In solns. of p_{H} 4.0 corn plants absorbed the NO_3 ions 4 times as rapidly as the NO_3 ions. Its presence in the soil enables grass to utilize the P_2O_5 in phosphorite.

Carbon dioxide as a stimulant and fertilizer. W. SCHMIDT. *Z. Pflanzenernähr. Düngung*, **4B**, 162-71 (1925).—Pine seeds germinated more rapidly at first in an atm. enriched with small amts. of CO_2 . The complete germination process was not benefited, however. Large amts. of CO_2 were injurious.

Ferric glycerophosphate and soluble ferric phosphate as sources of iron for soybean plants in solution cultures. R. P. MARSH. New Jersey Agr. Exp. Sta., *Ann. Rept.* 1923, 247-52.—The growth of plants in culture solns. receiving ferric glycerophosphate was greater than in solns. with ferric phosphate. Ferric phosphate produced Fe toxicity, while the same concn. of glycerophosphate produced normal plants. Plants in both solns. showed a marked decrease in yield with an increase in the amt. of $(\text{NH}_4)_2\text{SO}_4$ supplied to the solns.

Iron solubility tests in culture solutions at different p_{H} values. R. P. MARSH. New Jersey Agr. Exp. Sta., *Ann. Rept.* 1923, 252-6.—The soly. of ferric glycerophosphate, sol. ferric phosphate, ferric tartrate and ferrous sulfate in culture soln. of varying p_{H} values was studied. Difference in soly. of the various compds was noted. The soly. was influenced by the H-ion concn. of the solns. Ferric glycerophosphate can be used as a source of Fe for plants without danger in cultures in which the H-ion concn. is kept at a high level during the growth of the plants. In solns. where the H-ion concn. approaches the neutral point ferric tartrate is more effective.

The salts of manganese, of aluminium, and of iodine in the fertilization of the sugar beet. T. COSTA. *Staz. sper. agrar. ital.* **57**, 430-4 (1924).—Contrary to the report by J. Stoklasa (*C. A.* **18**, 1005), no favorable influence was revealed either by KI or by MnSO_4 (alone or with $\text{Al}_2(\text{SO}_4)_3$) on the wt. or on the sugar content of the sugar beet.

The influence of aluminium, manganese and iron salts upon the growth of sugar cane, and their relation to the infertility of acid Island soils. W. T. McGEORGE. *Exptl. Sta. Hawaiian Sugar Planters Assoc. Bull.* **49**, 95 pp (1925).—Salts of Al in concns. which are present in many acid Island soils exercise a retarding action and often a severely toxic action upon the growth of sugar cane. Mn salts have no effect upon the root growth of sugar cane in water cultures. The Lahania variety is less resistant toward Al toxicity than D1135 or H109. Acidity *per se* or H ion concn. of the intensity present in our most acid soils has no influence upon the growth of sugar cane. The Al salts which are present in such types retard the plant growth. Al toxicity is a direct toxic action and not a P_2O_5 deficiency, although increasing the P_2O_5 or K_2O reserve of the plant increases its resistance. Cane plants grown on acid soil contg. sol. Fe and Al are characterized by abnormal accumulations of these elements in the nuclei surrounding the xylem cells at the nodal joint of the stalk. Acid Island soils contg. sol. Al will respond markedly to sol. P_2O_5 applications. The P_2O_5 is rapidly fixed and only effective over a short period. There is also a marked response to heavy K_2O applications but not always to ordinary amts. CaO gave no immediate response but there was a greater residual stimulation in plant growth. These investigations prove that Al is a factor directly associated with the retarded growth of sugar cane on the acid Mauka lands and that both P_2O_5 and K_2O may exert an influence on plant growth other than as a direct plant food. It is not suggested that Al is the cause of "Lahania disease," but rather that it is one of the several factors involved in the low fertility of some Island sugar lands. A bibliography of 36 citations is included.

Chemical studies of the combined lead arsenate and lime-sulfur spray. R. W. THATCHER AND L. R. STREETER. New York Agr. Expt. Sta., *Bull.* **521**, 3-20 (1924).—In mixts. of Pb arsenate and in lime sulfur alone a definite chem. change took place with an increase in insol. material to double the original amt. The solid material contained some unchanged Pb arsenate, Pb sulfide, Ca arsenate and free S. The filtrate contained more sol. As than was present in the original mixt. This mixt. was less fungicidal and more harmful to foliage than the original. $\text{Ca}(\text{OH})_2$ added in proportion of 5 lbs. per 100 gallon of the mixt. prevented changes, and casein was a good protector. Expts. were conducted to study the effect of tobacco dust, and skim milk with $\text{Ca}(\text{OH})_2$ as protectors.

J. J. SKINNER

Manganese chlorosis of pineapples; its cause and control. M. O. JOHNSON. *Hawaii Agr. Expt. Sta., Bull.* 52, 38 pp. (1924).—The Mn of the highly manganiferous Hawaiian soils is present mainly in the form of MnO_2 ; H-ion detns. indicate that these soils are acid; $CaCO_3$ is absent. A series of expts. was conducted with rice grown in nutrient solns. to det. the effect of $MnSO_4$ and MnO_2 on the growth where various amts. of Fe were supplied from various sources. Preliminary expts. indicated that the effect of Mn depends largely upon the amt. of Fe supplied by the soln. When the nutrient soln. contained a normal amt. of Fe, $MnSO_4$ and MnO_2 caused a strong chlorosis and depression in growth. This chlorosis was overcome when the leaves were dipped in solns. of Fe salts or the amt. of Fe in the nutrient soln. excessively increased. The Mn-induced chlorosis is thus shown to be due to a depression in the assimilation of Fe or to a deficiency of Fe in the plant. It is altogether distinct from lime-induced chlorosis, due to $CaCO_3$, since it can and usually does, occur under acid conditions. Mn and $CaCO_3$ can each produce an additive chlorotic effect in the presence of the other. No evidence has been found to show that Mn exerts any stimulating effect on plant growth. With nutrient solns. contg. an excessive amt. of Fe, MnO_2 , by removing some of this harmful Fe, caused an increase in growth. NaOH titration curves are given for $FeCl_3$ and $FeSO_4$. Detn. of the soly. of Fe at different H-ion concns. shows that Fe^{+++} is completely pptd. while the soln. is still strongly acid and that Fe^{++} is sol under fairly alk. conditions. This difference in the soly. of Fe^{+++} and Fe^{++} affords an explanation of the manner in which Mn induces chlorosis. MnO_2 , either present as such, or formed from manganous salts, would keep the Fe present oxidized to the much more difficultly sol. ferric form. Field expts. are described in which solns. of Fe salts were applied to the leaves of pineapple plants on manganiferous Hawaiian soils, resulting in immediate cure of "toxic effects" of Mn and the resumption of normal growth. Such treatment has been widely adopted in practice.

P. R. DAWSON

Deposits of arsenic and copper on eating apples. ANON. *J. Ministry Agr.* 32, 519-53 (1925).—Detns. of As, Cu and Pb were made on the skin, stalk and calyx of 24 samples of eating apples from England, Canada and the United States. The results were somewhat higher with the American and Canadian apples, probably on account of later spraying in these cases. In 23 cases the quantities present were too small to be regarded as harmful even if the whole of the apples had been eaten. One Canadian sample was exceptionally high and suggested the need of caution in late spraying with Pb arsenate.

P. R. DAWSON

The Hoffmann system of sewage purification (KEPPNER) 14. Utilizing residual waters from pressing beetroot [as fertilizer] (U. S. pat. 1,552,737) 28. Treating waste organic mixtures containing N and K compounds [for fertilizer] (U. S. pat. 1,552 732) 16.

Fertilizer. M. IGAWA and ASAHI GARASU KABUSHIKI KAISHA. *Brit.* 219,748, Jan 29, 1923. Other inorg. colloidal materials such as oxides of Al or Mn or Al silicate are used in nitrogenous fertilizers instead of colloidal Mg silicate as specified in *Brit.* 218,401 (C. A. 19, 556).

Fertilizer. G. GARBIN and S. TONIOLO. *Brit.* 231,018. April 24, 1924. Natural phosphate in colloidal form is mixed with NH_4NO_3 or urea or both.

Fertilizer. J. S. G. TELFER. *Brit.* 231,021, May 3, 1924. A liquid fertilizer is formed from H_2O and a mixt. of NH_4 phosphate, $(NH_4)_2SO_4$, $NaNO_3$, $CaCO_3$ or Ca phosphate, kainite, NH_4NO_3 and K_2CO_3 .

Producing fertilizer, etc., from fish waste. H. KRAMER and A. REIFFUN. U. S. 1,550,268, Aug 18. See *Brit.* 225,949 (C. A. 19, 1620).

Insecticides. H. B. GOODWIN. U. S. 1,554,629, Sept. 22. A gum-resin deriv. such as gamboge is added to aq. insecticides which may contain Pb arsenate for spraying, in order to reduce the surface tension of the material. Tannin also may be used.

Insecticide. W. L. OWEN. U. S. 1,555,951, Oct. 6. An insecticide in jelly-like form comprises agar and a poison such as Ca arsenate.

Insecticide. R. C. ROARK. U. S. 1,553,112, Sept. 8. Powd. As is used for spraying or dusting purposes on plants, trees, etc.

Insecticide. C. O. NELSON. U. S. 1,553,002, Sept. 8. A mixt. for treating live stock as an insect repellent comprises salt 80, S 15 and lime 5%.

Disinfectant, insecticide, etc. FARBENFABRIKEN VORM. F. BAYER & Co. *Brit.* 232,249, April 10, 1924. A compn. of bactericidal, insecticidal and fungicidal properties is prepd. by treating a salt of a basic dye such as malachite green with arsenious or arsenic acid. Cf. C. A. 19, 3142.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Dehydration of rectified spirit by means of anhydrous calcium chloride. J. J. SUDBOROUGH AND P. R. AYYAR. *J. Indian Inst. Sci.* **8A**, 49-54(1925).—Distg. 88% alc. (by wt.) with $\frac{1}{6}$ its wt. of CaCl_2 (1 mol. CaCl_2 for 4.5 mol. H_2O) can give 95% by wt. alc. in 95% yield. Increasing the proportion of CaCl_2 slightly increases the concn. of the distillate, but decreases the yield. A second distn. with 1 mol. CaCl_2 for 1.1 mol. H_2O gives an 86% yield of 98% by wt. alc. Further concn. by distn. with CaCl_2 is tedious, and 99.5-100% alc. is best produced by treating the 98% alc. with 5% (on the wt. of the alc.) of fresh Ca turnings. The alc. retained by the CaCl_2 soln. during the 2nd distn. can be recovered by adding H_2O and distg. As a rule it does not pay to recover the CaCl_2 . A. PAPINEAU-COUTURE

Heat disturbance and temperature optimum in different strains of vinegar bacteria. M. WÜSTENFELD. *Deut. Essigind.* **39**, 331-2(1925).—A series of expts. is described showing that different strains of rapid vinegar bacteria exist which possess unlike temp. optima, and that the most efficient strain must be the one possessing the highest temp. optimum, because its greatest efficiency must be intimately connected with uninterrupted high heat production, as opposed to less efficient strains whose optimum oxidation activity suffers diminution at relatively low temps. W. O. E.

Evolution of free acidity during the fermentation of beers. VAN LAER. *Petit J. brasseur* 1925, 674; *Brasserie et malterie* **15**, 200-3(1925).—Free acidity is one of the most important factors involved in the stability of beer. Addn. of strong acids to decrease the p_H is delicate, and not advisable in practice. Increase in acidity during fermentation can depend on the compn. of the wort and on the nature of the yeast. The effects of the compn. of the wort are due mainly to the amt. of buffer compds. which van Laer measures by detg. the "buffer no.," $10/E(P_1 - P_2)$, in which P_1 and P_2 are the resp. p_H of the wort before and after addn. of 4 cc. 0.1 N acid per 100 cc. of wort, and E is the ° Balling. There should be enough buffer compds. to prevent undue increase in the p_H due to the alk. salts in the water, but not enough to prevent its decrease during fermentation. The buffer effects of amino acids were shown by comparison of worts prepd. with pure malt and with the same malt contg. 40% radicals (p_H 1.29, 2.40, resp.); this shows that worts with high amino-acid content will have too low an acidity for proper stability of the beer. Different brewing methods have little or no effect on the buffer no. of the wort. The action of the yeast on the p_H can vary within wide limits according to the compn. of the wort; and worts having widely different compns. can give beers having practically the same p_H , so that if the acidity of the beer is to be increased, it is preferable to add the acid after fermentation. A. P.-C.

Multiplication of yeasts in solutions of purified nutrients. MARGARET B. MAC DONALD. *Am. J. Hyg.* **5**, 622-34(1925).—The object of this paper is to suggest probable causes of failure to secure continuous multiplication of yeast cells in sugar-mineral salt nutrient solns. and of irregularities in the behavior of "bios" concentrates. The topics which are treated with much detail are: an adequate medium, the importance of acclimatization, the protection of yeast cells and the effect of "bios" concentrates and exts. The results are shown in 5 tables. No conclusions are drawn. L. W. R.

Corn whiskey and its constituents. H. M. STEVENSON. *Texas State J. Med.* **20**, 562-6(1925).—An examn. was made of seized illegitimate liquors. The compn. of the fusel oil from 200 samples of corn whiskey was approx. as follows (parts per 1000) isopropyl alc. 750, *n*-propyl alc. 180, isobutyl alc. 40, amyl alc. 20, undetd. 10. Fusel oil manufd. under controlled conditions contains 800-950 parts per 1000. S. concludes from the low amyl alc. content of illegitimate liquors and the relative non-toxicity of isopropyl alc. that such liquors are relatively non-toxic from the fusel oil point of view. The content of acetaldehyde is 300-400% of that found in bonded whiskies. Zinc and copper salts seldom occurred. The toxicity of the constituents of fusel oil is discussed. P. E. H.

Preparation of sparkling wines with varieties of Piedmont grapes. F. MARTINOTTI AND E. GARINO-CANINA. *Slaz. sper. agrar. ital.* **57**, 379-93(1924). Analyses of the wines at various stages of elaboration are given. ALBERT R. MERZ

K values from residues of molasses fermentation (U. S. pat. 1,555,512) 18.

Dealcoholizing beverages. C. I. CASPAR. U. S. 1,553,748, Sept. 15. A body of the beverage maintained in a tank and which may have a temp. of between -5° and

60° is drawn from and sprayed into a gaseous medium which is at a lower temp. than that of the beverage and is then returned to the supply tank. Alc. which is taken up by the gaseous medium is condensed from it and the dealcoholized gas is then returned for further circulation in contact with the sprayed beverage.

Treating waste organic mixtures containing nitrogen and potassium compounds. G. T. REICH. U. S. 1,552,732, Sept. 8. Waste mixts. such as distillery slop are treated with $(\text{NH}_4)_2\text{SO}_4$ to convert the K compds. to K_2SO_4 and form a product adapted for use as a fertilizer.

17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

An apparently new substance in lemon oil. GIOVANNI ROMEO. *Ann. chim. applicata* 15, 305-9(1925).—Lemon oil which had been deterpenated by concn. *in vacuo* and steam distn. deposited on the walls of the container on standing a cryst. substance, which in some cases redissolved later spontaneously (hydration and dehydration). Crystd. from boiling H_2O , this gave lustrous crystals having a bitter taste but no odor. Its soly. in boiling H_2O was about 7% and in cold H_2O about 1%. In MeOH, EtOH, EtO, EtOAc and C_6H_6 it was much more sol. and from dil. EtOH crystd. spontaneously. When crystd. from H_2O it m. 58°, the liquid being turbid because of the H_2O of hydration. After dehydrating over H_2SO_4 , the compd. m. 69-71° and b. 260° with slow decompn. It was dextrogyratory, a 6.24% EtOH soln. of the anhydrous compd. giving $[\alpha]_D +39.26^\circ$. The anhydrous form had the compn. $\text{C}_{10}\text{H}_{15}\text{O}_2$ but after crystn. from H_2O had the compn. $\text{C}_{10}\text{H}_{15}\text{O}_2 \cdot 3\text{H}_2\text{O}$. It gave a bright red color with concd. H_2SO_4 and an aq. soln. decolorized KMnO_4 and aq. Br. Evapn. of aq. Br contg. the compd. gave a marginal red-violet color with evolution of a thyme or mint odor and fumes of HBr. It could not be sapond. with alc. KOH but it reduced ammoniacal AgNO_3 soln. It gave no color with FeCl_3 . Treated with H_2SO_4 or HCl its satd. aq. soln. gave a 15% yield of a yellow oil which, extd. with Et_2O , had a thyme or mint odor and was insol. in KOH soln. Analysis showed that this oil was not formed through dehydration by the acids analogous to the formation of pulegone; but that it probably had the compn. $\text{C}_{10}\text{H}_{15}\text{O}_2$ like the solid and was an isomer. Further identification was impracticable.

C. C. DAVIS

Behavior of various aromatic substances in Vitali's reaction. H. W. VAN URK. *Pharm. Weekblad* 62, 926-32(1925).—Vitali's test for *atropine*, whereby evapn. of the sample with HNO_3 and treatment of the residue with alc. KOH gives an intense purple color, was applied to a large no. of aromatic derivs. The great majority of these gave color reactions, with the development of orange, red, green, brown or even violet color. The reaction is probably dependent on the nitration of a Ph group. It is readily obtained when the Ph is linked to N, and the color is intensified by the presence of OH groups. Where the Ph is linked to C, as in BzOH, cinnamic acid, $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$, saccharin, luminal, etc., no color develops except a yellow in the case of phenols, ketones and aldehydes. Polyatomic phenols react explosively with the HNO_3 . A. W. DOX

An introduction to the evaluation of our medicinal agents. P. VAN DER WIELEN. *Pharm. Weekblad* 62, 942-61(1925).—A popular lecture on drug assay by means of phys., chem. and physiol. properties. A. W. DOX

Digitalis and digitalis preparations. J. S. MEULENHOFF. *Pharm. Weekblad* 62, 961-82(1925).—A study of the activity of digitalis preps. as influenced by the source of the crude drug, the method of extn. and the age of the prepn. A. W. DOX

Characteristic reactions of luminal. F. RANWEX. *J. pharm. Belg.* 6, 501-5(1924).—Reduce the nitroluminal, prepd. by adding to the mixt. granulated Zn + dil. H_2SO_4 . When soln. is complete decant the clear liquid and cool it to 5°. Add to the cold liquid about 0.10 g. of KNO_2 dissolved in H_2O . Diazoluminal forms immediately and remains in soln. at this diln. This is identified by the following color reactions: (1) On the addition of a few particles of β -naphthol to a portion of the soln., an intense blood-red coloration is produced. (2) The addition of α -naphthol followed by NaOH to alkyl. gives an intense orange-red color. (3) Sodium β -naphthol-3,6 disulfonate gives a cherry-red color. (4) Phenol gives a deep brown color. (5) Resorcinol gives an intense orange-brown color. (6) Phloroglucinol gives a brownish red color. (7) Guaiacol gives a yellow-brown color. (8) Potassium *o*-guaiacolsulfonate (thiocol) gives a yellow-brown color. (9) Thymol gives a brown-yellow color. (10) Eugenol gives a bright cherry-red color. No results were obtained with vanillin. Hy-

droquinol and salicylic acid do not react. Pyrogallol and gallic acids do not produce characteristic colors. Cf. *C. A.* **18**, 2408. A. G. DuMEZ.

Otto of rose from the analyst's point of view. W. H. SIMMONS. *Perfumery Essent. Oil Record* **16**, 341-4 (1925).—The principal subjects discussed are: nature of raw material, process of distn., and distn. plant employed, as constituting the 3 important factors which have to do with the question as to what genuine otto of rose actually is. Further points considered are: compn. of otto of rose, standards and examn., sp. gr., optical rotation, refractive index, melting point, sapon. value, total alcs. W. O. E.

Anatomical critique of officinal seeds and fruit. FRITZ NETOLITZKY. *Pharm. Monatshefte* **6**, 149-55 (1925).—The examn. of the cork and cuticular membranes of some 20 different products is discussed, notably with respect to their behavior toward potash, HNO_3 - KClO_3 mixt. and CrO_3 . W. O. E.

New color test for amylene hydrate (tertiary amyl alcohol). L. EKKERT. *Pharm. Zentralhalle* **66**, 599 (1925).—On mixing 0.5 cc. of a 5% alc. soln. of amylene hydrate with 5 cc. concd. H_2SO_4 and then superimposing on the warm yellow mixt. a 5% soln. of tartaric acid, a rose-red color develops at the surface of contact, the entire upper layer finally acquiring this tint. The tartaric acid may be replaced by guaiacol, K guaiacolsulfonate or resorcinol. The color is still pronounced with only 1 drop of 5% alc. amylene hydrate. W. O. E.

Travancore essential oils. VI. From *Cymbopogon caesius* Stapf (Inchi grass). KISHORI LAL MOUDGILL. *Quart. J. Indian Chem. Soc.* **2**, 23-38 (1925); cf. *C. A.* **19**, 2388.—Oils distd. from both varieties (red and white) of this grass from the same locality and at the same time showed: d_4^{20} 0.9130, 0.9110; n_D^{20} 1.4820, 1.4815; $(\alpha)_D^{20}$ -3.60° , -40.0° ; acid no. nil; ester no. 11.4, 9.2; ester no. after acetylation 121.8, 117.4, resp. The product presents a sweet smelling oil, quite different in character from the oils obtained from similar grasses but resembles palmarosa oil in odor. It occurs both in the flowers and leaves, undergoes no change on storage, that from the leaves being fairly uniform during different stages of plant growth, the flower oil being richer in sesquiterpenes and having a much lower Ac value. The constituents of the oil are *l*-limonene, *l*-camphene, *l*-borneol, *l*-terpeneol, a bicyclic sesquiterpene (d_4^{20} 0.9064, n_D^{30} 1.5005, $(\alpha)_D^{30}$ -12°), a tertiary sesquiterpene alcohol ($\text{C}_{15}\text{H}_{26}\text{O}$), and a terpene alcohol as yet uncharacterized. In addn the presence of an aldehyde yielding a Na salt of sulfonic acid on treatment with NaHSO_3 , esters of acetic, butyric and an unsatd. acid $\text{C}_{16}\text{H}_{30}\text{O}_2$ was noted. W. O. E.

The evaluation of insulin preparations. F. DEPISCH, F. HOGLER AND K. UEBERACK. *Klin. Wochschr.* **3**, 1064-5 (1924).—Insulin preps. are frequently mislabeled as to strength. This is probably due to faulty methods of assay. The authors suggest changing the value of 1 unit to that quantity of insulin that will reduce the blood sugar value to at least 45 mg. % and produce cramps in 3 out of 4 animals. The labeled and actual strengths of 20 preps. from various manufacturers are given. M. H.

Evaluation of hypophyseal extract using the frog reaction of Hogben and Winton. M. KOCHMANN AND W. WAGNER. *Klin. Wochschr.* **4**, 1503-4 (1925); cf. Treuter, *Zentr. Gynakol.* **1924**.—The dark coloration of the skin that occurs in frogs after an injection of hypophyseal ext. can be used as a crude method for evaluating such exts. This method is inferior to the uterine strip method. MILTON HANKE.

A new purgative, the oil of the "castor oil fish," *Ruvettus*. E. W. RUDGER. *Bost. Med. Surg. J.* **192**, 107-11 (1925).—This fish is a deep water fish of rather wide distribution but not very common. Its flesh and bones are rich with a limpid oil which causes a mild diarrhea when the former are eaten. No attempt has been made to analyze this oil and ascertain the purgative agent. JULIAN H. LEWIS.

Chemical composition of the stem bark of purgative buckthorn (*Rhamnus cathartica* L.). M. BRIDEL AND C. CHARAUX. *Ann. chim.* [10], **4**, 79-120 (1925).—The bark of *Rhamnus cathartica* L. contains an unstable glucosidic complex, *rhamnarticoside*, which is dissociated by cold water giving a crystd. insol. glucoside, *rhamnicoside* (I) (new), and sol. glucosides hydrolyzable by the enzyme of *Rhamnus* seeds. The products of hydrolysis of the glucosides gave the following cryst. compds.: *primeverose*, *emodin*, and another hydroxymethylanthraquinone compd., m. 234° . I has $(\alpha)_D$ -78.12° , crystallizes in needles, is insol. in water, with alkalis and alk. earths gives crystd. colorless compds., which are slightly sol. in water, very readily decomposed by light and air into violet, blue or green compds. and are the base of the coloring matter known as "Lo-Kao" or Chinese green. I reduces Fehling soln. (1 g. = 0.206 g. glucose), is hydrolyzed by H_2SO_4 to an equimol. mixt. of glucose and xylose together with an insol. crystd. compd., *rhamnicogenol* (II) (new), is readily hydrolyzed by boiling water to II

and primeverose, and is also hydrolyzed to II and primeverose by the enzyme powder of *Cornus sanguinea* L., in spite of the practical insolv. of both I and the enzyme. II is a hydroxymethylanthraquinone compd., does not give with alkalis in presence of air the violet-blue coloration of I, gives a pink soln. with green fluorescence in presence of alkali, and is oxidized to a red soln. by excess of alkali. Analysis and reactions point to the formula $C_{20}H_{20}O_{15} \cdot 4H_2O$. Acid hydrolysis gives glucose, xylose and rhamnicogenol; fermentative hydrolysis gives primeverose and rhamnicogenol. II is thus a *pentahydroxymethylanthranol*. I has been identified in *R. utilis* (DCne), *R. infectoria* L., *R. Saxatilis* (Jacq), *R. oleoides* L., *R. italicus* (Horitecole), *R. cathartica* L., all of which are thorny and have an easily detachable epidermis; it is not found in *R. frangula* L., *R. alternus* L., *R. alpina* L., *R. japonica* (Maxim), *R. Billardii* (Horticole), none of which has thorns, and all of which have adherent epidermis. An enzyme which hydrolyzes I was isolated from the bark of *R. cathartica*.

A. PAPINEAU-COUTURE

Perfumes, natural and synthetic. W. B. GARNER. *Chem. Eng. Mining Rev.* 17, 201-5 (1925).—Brief general description of their method of manuf. A. P.-C.

Kachi-grass oil. B. S. RAO AND J. J. SUDBOROUGH. *J. Indian Inst. Sci.* 8A, 9-27 (1925).—Steam distn. of *Cymbopogon caesius* Stapf gave the following yields (on the dry basis): whole grass 0.22-0.53%, stalks and leaves 0.16-0.20%, flower-heads 1.10-1.61%, of oil which showed $d_{15}^{25} 0.9181-0.9789$, $n_D^{20} 1.4838-1.4907$, $[\alpha]_D^{25} +9.9$ to -62.5° , acid value 0.5-9.2, sapon. value 12.0-32.4, sapon. value after acetylation 114.6-172.3, total alcs. (as $C_{10}H_{18}O$) 34.5-54.4%. The yield of oil from mature and immature flower-heads is much the same. The oil becomes richer in oxygenated compds. as the flowers ripen, resulting in gradual increase in total alcs. and esters with corresponding increase in soly. in 70% alc. The d. and n tend to rise as the grass matures. The properties of the oils from the stalk and flower-heads do not vary much. Oil from green flowers has a relatively high l -rotation. Rotation seems to be due to the presence of d - or l -limonene, as high rotation is due to the lower terpene fraction and not to the higher alc. fractions. The above consts fall within the limits usually given for ginger-grass (*C. Martini sofua*) oil. Dipentene, limonene, geraniol and perillal alc. were identified. Insol. Kachi-grass oil can be rendered sol. by reducing the terpene content to 30%, either by removal under reduced pressure or by steam. Higher-boiling fractions are also insol. in alc., and freshly distd. oils, if insol. can often be rendered sol. by rejecting part of the higher-boiling fractions (usually the last 12%); but oils which have been kept for some time do not give sol. products under such treatment. On storage n rises and $[\alpha]$ falls, the change being the more marked in the alc. fractions than in the terpene fractions; but the total alcs. (via acetylation) in the oil does not change appreciably.

A. PAPINEAU-COUTURE

Essential oil of *Cyperus rotundus*. B. S. RAO, P. B. PANICKER AND J. J. SUDBOROUGH. *J. Indian Inst. Sci.* 8A, 39-47 (1925).—Steam distn. of tubers of *Cyperus rotundus* Linn., disintegrated through a 0.25-in. screen, gave 0.53-0.86% of oil with $d_{15}^{25} 0.9828-0.9907$, $[\alpha]_D^{25} +20.1$ to $+42.8^\circ$, $n_D^{25} 1.5126-1.5156$, acid value 2.1-3.4, sapon. value 11.7-16.1, Ac no. 66.5-98.1, which gave no absorption with 30% $NaHSO_3$ nor with 5% KOH. The lower fractions contain at least 2 sesquiterpenes with mol. refraction 65.5. Two or more alcs. are present. Total alcs. (as $C_{15}H_{26}O$) are about 30%. They do not react with phthalic anhydride, and are presumably tertiary. In addn. to alcs., the higher fractions contain large quantities of neutral substances, presumably hydrocarbons. No pure substances could be isolated from the oil. A. P.-C.

Notes on some Indian essential oils. B. S. RAO, J. J. SUDBOROUGH AND H. E. WATSON. *J. Indian Inst. Sci.* 8A, 143-88 (1925).—Steam distn. of the leaves of *Calitris rhomboidea* R. Br. (*Frenela rhomboidea*, Endl.) yielded 0.17% of oil with $d_{15}^{25} 0.8715$, $n_D^{25} 1.4703$, $[\alpha]_D^{25} -29.1^\circ$, sapon. value 47.1, esters (as $C_{10}H_{17}OCOMe$) 16.5%, contg. nearly 50% terpenes. Distn. of the oil at 683 mm. gave: 160-70° 43.3, 170-80° 11.9, 180-200° 17.0, residue 27.0%. *Inchi grass oil* from Travancore, *botha grass oil* from Madras and *bode grass oil* from Mysore had: $d_{15}^{25} 0.9200, 0.9038, 0.9231$; $n_D^{25} 1.4849, 1.4748, 1.4831$; $[\alpha]_D^{25} -40.0^\circ, +39.9^\circ, -24.7^\circ$; acid value —, —, 1.3; sapon. value 5.9, 44.7, 45.5; sapon. value after acetylation 98.4, 120.7, 112.7; total alcs. (as $C_{15}H_{26}O$) 29.2, 36.5, 34.4%, resp. On distn. under 683 mm., *inchi grass oil* gave 28.5% at 190-70°, 30.0% at 240-75°, both a grass oil gave 40% at 150-80°, 30% at 180-240° and 20% at 240-60°. Steam distn. of the roots of *cus-cus grass* (*Veliveria zizanoides*, Stapf) from Bangalore gave 0.63 and 0.79% of oil from first quality roots, and 0.20 and 0.28% from second quality, the resp. higher yields being obtained by soaking in water before distn. Two samples of the crude oil, and 2 of the redistd. oil had: $d_{15}^{25} 1.0028, 1.0030$,

1.0008, 1.0040; n_D^{25} 1.5214, 1.5210, 1.5210, 1.5191; $[\alpha]_D^{25}$ —, +25.5°, +24.2°, —65.0°; acid value 21.4, —, —, 41.2; sapon. value 31.0, 33.8, 29.7, —; ester value 10, —, —, —; ester value after acetylation 102.3, —, —, 146.8; total alcs. (as $C_{16}H_{34}O$) 43.4, —, —, 64.8, resp. Distn. under 10 mm. pressure gave: 145–65° 16.6% ($[\alpha]$ —4.3°), 165–75° 24% ($[\alpha]$ +16.0°), 175–80° 16.6% ($[\alpha]$ +26.6°), 180–95° 18.3% ($[\alpha]$ +36.2°), 195–215° 8.3%, 215–40° 8.3%, residue 6.6%. 85% of the residue is sol. in 98% (by wt.) EtOH, and the soln. (0.57%) has $[\alpha]$ +52°. Bangalore oil is midway between German (Semmler, C. A. 7, 213) and Reunion distd. oil as regards proportion of high-boiling constituents. No highly *d*-rotatory resin was found (cf. Singh, C. A. 9, 234). Steam distn. of dry, peeled, disintegrated *calamus roots* (*Acorus calamus*, Linn.) from Coimbatore district yielded 1.5% of oil with d_{15}^{15} 0.0694, n_D^{25} 1.5030, $[\alpha]_D^{25}$ +6.2°, acid value 1.4, sapon. value 5.1, sapon. value after acetylation 16.6, sol. at 8° in 1.5 vol. of 70% alc. Distn. under 10 mm. pressure gave: below 130° nil, 130–40° 13.3, 140–50° 13.3, 150–7° 66.6, residue 3.3%. Pinene, camphene and camphor are apparently absent. The *d*. is considerably higher and $[\alpha]$ somewhat lower than those of known com. samples of the oil. Steam distn. of waste *ginger* gave 3.54% of oil with d_{15}^{15} 0.8822, n_D^{25} 1.4898, $[\alpha]_D^{25}$ —39.2°, acid value 2.1, ester value 7.7, ester value after acetylation 49.8. Distn. under 685 mm. (at which the oil undergoes decompn.) gave: to 150° 1.4, 150–200° 5.0, 200–40° 12.3, 240–65° 40.0, 265–80° 29.8, residue 9.7%. The consts. are within the limits for ginger oil, except for the presence of a larger proportion of alcs. Steam distn. of disintegrated rhizomes of *Curcuma zedoaria*, Roscoe, yielded 1.01% (on the dry basis) of oil with d_{15}^{15} 0.9863, n_D^{25} 1.5024, acid value 2.1, sapon. value 9.8, sapon. value after acetylation 73.4, aldehydes (absorption with Na_2SO_3) 3.5, sol. in 1.5 vol. of 80% alc. at 15°. Distn. at 685 mm. pressure gave: 165–80° 11, 180–230° 23, 230–90° 56%. Steam distn. of *Elettaria cardamomum*, Maton yielded 2.42–6.45% of oil from seeds only, and 4.90–6.45% from seeds and pericarp. Crushing the material before distn. shortens the time of distn. and reduces steam consumption, but does not affect the yield of oil. The oils had d_{15}^{15} 0.9264–0.9349, n_D^{25} 1.4603–1.4620, $[\alpha]_D^{25}$ +15.1 to +44.0°, acid value 0.36–1.3, sapon. value 9.6–15.6. The low $[\alpha]$ observed in certain instances is possibly due to immaturity of the fruit. Steam distn. of *cubeb*s (*Cubeba officinalis*, Miq., *Piper cubeba*, Linn.) yielded 11.85% of light green oil with d_{15}^{15} 0.9167, n_D^{25} 1.4894, $[\alpha]_D^{25}$ —29.9°, sapon. value 0.5, sapon. value after acetylation 24.1, sol. in 5 vol. of 90% alc. at 16°. Fractionation at 685 mm. pressure gave: 140–70° 5, 170–225° 20, 225–45° 15, 245–65° 45, 265–80° 10, residue and loss 5%. Steam distn. of different portions of a 40-yr. old *camphor tree* gave: camphor % on total oil from leaves 30.5–43.0, from twigs 20.0–25.2, bark from branches 5.0, branches 5.9–10.9, main stem and large branches 12.0, roots 24.2, stump 17.5–25.0; camphor % on dry material from leaves 0.39–0.90, from twigs 0.17–0.33, bark from branches 0.02, branches 0.06–0.13, main stem and large branches 0.30, roots 1.91, stump 1.06–1.44; camphor oil % on dry material from leaves 0.32–1.20, from twigs 0.71–0.94, bark from branches 0.48, branches 1.04–1.13, main stem and large branches 2.0, roots 6.04, stump 4.36–5.04; total volatile oil % on dry material from leaves 0.82–2.10, twigs 0.88–1.27, bark from branches 0.50, branches 1.17–1.56, main stem and large branches 1.84–2.30, roots 7.95, stump 5.80–6.10. The results are compared in detail with numerous previously published results. Analytical consts. of some of the camphor oils after sepn. of the camphor, and of others before sepn. of the camphor, resp., gave: d_{15}^{15} 0.9106–0.9290, 0.9276–0.9518; n_D^{25} 1.4678–1.4793, 1.4680–1.4833; $[\alpha]_D^{25}$ 6.4–26.0°, 5.8–24.5°; acid value 0.6–2.3, 1.1 (only one value given); sapon. value 0.6–7.1, 1.0–4.0; sapon. value after acetylation 25.0–49.3, 25.7–40.0. A small proportion of safrole was found in the oils obtained from roots, stump and thick branches, but none from twig and leaf oils. Steam distn. of sun-dried carpels of *Zanthoxylum rhetsa*, D. C. yielded 5.8% (on the dry basis) of oil with d_{15}^{15} 0.8562, n_D^{25} 1.4663, $[\alpha]_D^{25}$ —32.6°, acid value 1.2, sapon. value 5.9, sapon. value after acetylation 49.3. Distn. of the oil at 7 mm. pressure gave: 48–52° 72.3% (n_D^{25} 1.4660, $[\alpha]_D^{25}$ —35.5°), 52–4° 16.0% (n_D^{25} 1.4660, $[\alpha]_D^{25}$ —32.8°), 54–90° 5.0% (n_D^{25} 1.4693, $[\alpha]_D^{25}$ —14.7°), residue 5.5% (n_D^{25} 1.4835), clearly indicating that nearly 90% of the oil consists of terpenes, chiefly *sabinene* (Wallach, C. A. 2, 1830). Extn. with petrole ether of the crushed pepper-like seeds of *Z. rhetsa* yielded 29.7% (on the dry basis) of oil contg. 2.7% (on the dry seeds) of a solid glyceride, m. 53°, sapon. no. 227.2. The liquid portion of the oil was not volatile with steam. Pcp. of *Citrus bigaradia* (Risso), by the ordinary sponge method gave 0.25–0.32% oil with d_{15}^{15} 0.8629–0.8658, n_D^{25} 1.4737–1.4749, $[\alpha]_D^{25}$ +84.7° to +88.2°, non-volatile residue 9.9–12.1%. Extn. of the pips with Et₂O gave 30.5

and 21.4% (on the dry basis) of fixed oil, which had, after sepn. of the solid portion, d_{15}^{15} 0.9243, 0.9257; n_D^{40} 1.4650, 1.4652; acid value 3.1, 2.9; sapon. value 198.5, 198.1; I value 94.0, 94.1. Steam distn. of *coriander* (*Coriandrum sativum*, Linn.) fruit yielded 0.25% (on the dry basis) of oil with d_{15}^{15} 0.8721, n_D^{25} 1.4576, $[\alpha]_D^{25}$ +13.7°, acid value 0.26, sapon. value 31.0, sapon. value after acetylation 45.4, sol. in 3 vol. of 70% alc. at 15°. Steam distn. of white *cumin* (*Cuminum cyminum*, Linn.) fruit yielded 2.35% of oil with d_{15}^{15} 0.8945, n_D^{25} 1.4910, $[\alpha]_D^{25}$ +3.6°, aldehydes (NaHSO₃ absorption) 16%, sol. in 11 vol. of 80% alc. at 20°. Steam distn. of *dill* (*Anethum sowa*, Roxb.) fruit yielded 2.17% of light oil and 1.02% of heavy oil, which had d_{15}^{15} 0.9313, 1.0935; n_D^{25} 1.4853, 1.5154; $[\alpha]_D^{25}$ +58.2°, —; carvone (absorption with NaHSO₃) 17%, —. The combined light and heavy oils had d_{15}^{15} 0.9785, n_D^{25} 1.4943, $[\alpha]_D^{25}$ +47.6°, carvone 19.5%. If the dill-apiol is removed from Indian dill oil, the consts. approx. to those of the European oil. Steam distn. of *Indian fennel* (*Foeniculum panmorium*, D. C.) yielded 0.53–0.82% (on the dry basis) of oil with d_{15}^{15} 0.9744–0.9767, n_D^{25} 1.5355–1.5383, $[\alpha]_D^{25}$ 11.7–16.9°, congealing point +5.5 to 9.0°, sol. in 1 vol. of 90% alc. at 6–10°. Fractionation at 7 mm. pressure gave: 54–75° 9.7% (n_D^{25} 1.4740, $[\alpha]_D^{25}$ +58.1°), 75–90°, 9.7% (n_D^{25} 1.5025, $[\alpha]_D^{25}$ +34.6°), 90–100° 7.0% (n_D^{25} 1.5031, $[\alpha]_D^{25}$ +9.5°), 100–1° 66.6% (n_D^{25} 1.5560, $[\alpha]_D^{25}$ nil, m. p. 21°), residue and loss 7.0%, indicating the presence of over 70% of anethole. Fenchone (6%) was found in the oil, but it is improbable that methyl-chavicol is present in any large quantity.

A. PAPINEAU-COUTURE

The new Swedish pharmacopeia. H. WASTENSON. *Svensk Farm. Tids.* 29, 393(1925).—Review.

A. R. ROSE

Hemolysin. K. A. KARSMARK. *Svensk Farm. Tids.* 29, 378–82(1925).—A system of evaluating the hemolytic potency of drugs. The drug of given concn. (0.001–1.0%) is dild. with saline soln. and 1 cc. added to 1 cc 2% blood-cell suspension making 2 cc. The tubes are arranged in the order of the increasing cc. (0.05–1.0) of the infusion and the first tube showing complete hemolysis is the key to the index table. For instance the 5th tube in the increasing scale contains 0.55 cc. 0.005% decoction of saponin. In table, p. 382, under vol. of hemolysin find 0.55, follow on line to column for 0.005% and find given 72,700. This number is the index number for the sample examd. A. R. R.

A chemical examination of oleoresin of Indian valerian root. K. BULLOCK. *Pharm. J.* 115, 122–5; *Chemist & Druggist* 103, 170–1(1925).—A large lot of Indian valerian root yielded to petroleum spirit 1.64% of ext., of which 47.4% the oleoresin (A), was sol. in 70% EtOH (cf. C. A. 18, 3451). Small samples of genuine root have yielded 2–3% of A. No alkaloid was found in A, but this and the root contain quite large amounts of free acids, mainly *valeric acid*; the others are a rather complex mixt. of satd. and unsatd. fatty acids. By the action of acids, alkalies and heat, A resinifies easily, caused in part by oxidation of the unsatd. fatty acids. The fatty matter insol. in 70% EtOH fails to give tests for glycerol. Unsapond. matter seems to contain a liquid hydrocarbon, b. p. about 120° (–140°) and a semi-solid alc., b. p. about 240°. S. W.

Notes on the quinine sulfate monograph of the Brit. Pharm. Codex 1923. B. F. HOWARD AND OLIVER CHICK. *Pharm. J.* 115, 125–7, 176; *Chemist & Druggist* 103, 172(1925).—The descriptions of Keller's test for cinchonidine, etc. in the Codex 1923 and the Brit. Pharm. 1914 are worded differently, involving a difference in the temp. of the 20 cc. of H₂O added: 60–65° (Brit. Pharm.), 15° then heating the mixt. to 60–65° (Codex). By the latter procedure, if official, highly pure quinine sulfate would appear to be below standard. Also, the soly. in dil. acids given in the Codex is impossible to attain, because of an oversight in not allowing for the reduced strengths of the acids in the present Codex as compared with that of 1911. S. WALDBOTT

Disinfectant (Brit. pat. 232,249) 15. Esters of 4-hydroxypiperidine (Brit. pat. 232,206) 10. Bu esters of phthalic acid (U. S. pat. 1,554,032) 10.

Medicinal composition. G. L. COUSINEAU. U. S. 1,554,155, Sept. 15. An aq. liquid contg. both sol. and insol. portions of testical gland is used for hypodermic injection for "practically every type of disease known."

Medicinal compounds from yeast and dyes. HACO-GES. AKT.-GES. Brit. 231,120, June 21, 1924. The process described in Brit. 230,404 (C. A. 19, 3351) is extended to the use of other thiazine dyes, e. g., yeast may be treated with Indochromine RR and the product further treated with NaBr; on filtering, washing and drying, the leuco compds. first formed are oxidized.

Sterilizing medicinal proteins, etc. C. A. MILLS. U. S. 1,556,120, Oct. 6. Materials such as serums, enzymic preps. or globulins are treated with HgCl_2 and the soln. is subsequently cleared by converting the Hg proteinate into the protein and a Hg compd. which is sol. and is removed by dialysis.

Isotonic solution. H. PORRATZ. U. S. 1,554,027, Sept. 15. A sterilized isotonic soln. adapted for medicinal purposes comprises a salt soln. and a soln. of a Ce compd. such as CeI_2 , the 2 solns. being of the same osmotic pressure.

Remedy for treating tumors, etc. L. LILIENFELD. U. S. 1,555,016, Sept. 29. A remedy for malignant tumors comprises aurous selenide, Au_2Se , together with Et or Me ethers of starch or cellulose or a similar carbohydrate ether which is sol. in cold but not in hot H_2O . Selenides or tellurides of Ir, Pd, Os, Pt, Hg, Ag, Cu or Sn also may be used.

Therapeutic substances from ovaries, etc. SOC. ANON. POUR L'IND. CHIM. À BÂLE. Brit. 226,372, Dec. 29, 1923. Physiologically active substances of ovaries, corpora lutea or placentas are obtained in concd. form by dissolving in a volatile solvent such as acetone and MeOH a prepn. such as described in Brit. 113,311 (C. A. 12, 1337) and treating the soln. with basic Pb acetate or cooling it to a temp. below -20° (or both).

Antitoxic serums. A. R. DOCHEZ. Brit. 232,181, April 14, 1924. In making serums for treatment of scarlet fever or other diseases for which a sol. toxin cannot be prepd. by cultivation of the bacteria *in vitro* or within an animal body in the usual manner, a fluid agar or similar compn. is injected into an animal, e. g., a horse, followed by injection of a bacterial culture, repeating this procedure and then obtaining the serum. Before these injections, in the case of *streptococci scarlatinae*, a horse is preliminarily tested for glanders and injected with tetanus antitoxin. The culture used for immunizing is subjected to frequent passage culture through mice and is preserved on ice in rabbit's blood broth.

Centrifugal apparatus for treating serum. E. R. ALEXANDER. U. S. reissue 16,162, Sept. 8. See original pat. No. 1,539,102, C. A. 19, 2262.

Chlorine-containing composition adapted for use in disinfecting. L. D. MATHIAS. U. S. 1,555,474, Sept. 29. Sufficient NaOH soln. is added to a soln. of di-Na phosphate to form the normal phosphate, and a NaOCl soln. is then added to form a compn. which contains at least 1% available Cl.

Menthol and related compounds. RHEINISCHE KAMPFER-FABRIK GES. Brit. 231,827, April 4, 1924. The mixt. of menthol and isomenthol obtained by the catalytic hydrogenation of thymol is sepd. by fractional distn., *in vacuo* or at atm. pressure, the isomenthol distg. first. The isomenthol is then subjected, either alone or with more thymol, to further hydrogenation, or is first dehydrogenated to isomenthone and the latter then hydrogenated.

Cod-liver-oil tablets. B. L. EICHER. U. S. 1,552,549, Sept. 8. Charcoal is mixed with reduced Fe and other medicines and pills or tablets formed of this mixt. are treated with a soln. of cod-liver oil in a volatile solvent such as ether and the solvent is then evapd.

Substituted barbituric acids. FARBENFABRIKEN VORM. F. BAYER & CO. Brit. 231,150, March 21, 1924. Δ^2 -Cyclohexenylethylbarbituric acid is prepd. by treating the Na compd. of monoethylmalonic acid ester with 1-bromo- Δ^2 -cyclohexene and reacting upon the resulting Δ^2 -cyclohexenylethylmalonic acid ester with urea. Δ^2 -Cyclohexenylallylbarbituric acid is similarly prepd. from the monoallylmalonic acid ester. The Na compd. of Δ^1 -cyclohexenylcyanoacetic acid ester is treated with EtI and the resulting Δ^1 -cyclohexenylethylcyanoacetic acid ester added to a soln. obtained by boiling guanidine sulfate with Na in alc., thus producing Δ^1 -cyclohexenylethylbarbituric acid; Δ^1 -methylcyclohexenyl- and Δ^1 -cyclopentenylcyanoacetic acid esters are transformed in the same way into Δ^1 -methylcyclohexenylethyl- and Δ^1 -cyclopentenylethylbarbituric acids, resp. The products are hypnotics.

Pyrazolone-barbituric acid compound. P. PFEIFFER. Brit. 231,512, Mar. 27, 1924. A double compd., in mol. proportions, of diethylbarbituric acid and 4-dimethylamino-2,3-dimethyl-1-phenyl-5-pyrazolone is prepd. from a soln. of the components. It is an analgetic and soporific.

2-Acetoxy-4-methoxybenzoic acid. FARBENFABRIKEN VORM. F. BAYER & CO. Brit. 231,886, April 4, 1924. This compd., an antipyretic, is made by acetylating 4-methoxy-2-hydroxybenzoic acid. Its alkali salts also possess antipyretic properties.

Thioglycolic acid derivative containing antimony and calcium. H. HAHN. U. S. 1,555,663, Sept. 29. A compd. of the formula $\text{Sb}_2(\text{S}-\text{CH}_2-\text{COO})_2\text{Ca} \cdot 3\text{H}_2\text{O}$ is obtained by reaction of thioglycolic acid, S_2O_3 and CaCO_3 . It is a whitish powder, sol. in H_2O to a slight alk. reaction, and is a spirilloicide.

β -Diethylaminoisohexyl *p*-aminobenzoate. P. KARRER. U. S. 1,555,217, Sept. 29. This compd. is made by reacting on $\text{Me}_2\text{CHCH}_2\text{CH}(\text{NEt}_2)\text{CH}_2\text{OH}$ with $p\text{-O}_2\text{NC}_6\text{H}_4\text{COCl}$ and reducing the resulting product. It is similar in effect to cocaine and has a stronger action than "novocaine."

Hydroxy- and alkoxyacridinium compounds. L. CASSELLA & Co., Ges. Brit. 218,542, Oct. 30, 1923. Hydroxy- and alkoxyacridinium compds. are prepd. by treating hydroxyacridines described in Brit. 217,715 (C. A. 19, 380) with alkylating or aralkylating agents in the absence of an acid-binding agent. E. g., 3,6-dihydroxy- and 3,6-dimethoxy-10-methylacridinium chlorides are prepd. by treating the corresponding acridines with *p*-toluenesulfonic methyl ester and boiling the toluenesulfonates with HCl to obtain the methochlorides. Ethyl-, benzyl- and hydroxy-ethyl-acridinium chlorides are obtained by treating 3,6-dimethoxyacridine with *p*-toluenesulfonic ethyl ester, benzyl chloride and ethylene chlorohydrin, resp. The alkylations are carried out in PhNO_2 soln. The products are antiseptics and show but little dyeing properties.

Diacetoxymercuri-4-nitro-*o*-cresol. G. W. RAIZISS. U. S. 1,554,293, Sept. 22. $\text{C}_6\text{H}_4(\text{OH})(\text{NO}_2)(\text{HgOAc})_2$ is made by dissolving 4-nitro-*o*-cresol in a hot aq. NaOH soln. and reacting on it with a hot acid $\text{Hg}(\text{OAc})_2$ soln., pptg. with NaOH. It is a brownish yellow powder insol. in H_2O , MeOH and ether, but sol. in a dil. aq. alkali metal hydroxide soln. It is a therapeutic germicide.

Compound of cinchona alkaloid with 2-phenylquinoline-4-carboxylic acid. H. W. RHODEHAMEL. U. S. 1,353,266, Sept. 8. Quinine or other cinchona alkaloid and 2-phenylquinoline-4-carboxylic acid are united in mol. proportions, e. g., by mixing the solns. in alc. together and crystg. The resulting compd. (with quinine) m. 174° .

Mercury derivatives of phthaleins. E. C. WHITE. U. S. 1,549,942, Aug. 18. HgO is caused to react in aq. suspension on a sol. salt of a phthalein, e. g., the Na salt of phenolphthalein or fluorescein, thus forming a product which may be used by injection as an anti-syphilitic.

Calcium salt of the organic phosphorus compound contained in milk casein. S. POSTERNAK. U. S. 1,555,517, Sept. 29. A white powder of "indifferent" taste, sol. in H_2O and contg. P 4.5–5, Ca 10–11 and N about 11.5%, is obtained by digesting milk casein with trypsin in a dil. NH_3 soln. until sepn. of fatty acids occurs, pptg. the filtered digestion liquid with a sol. Ca salt and about an equal vol. of alc., redissolving the pptd. Ca salt of the P compd. thus obtained in H_2O , repptg. with alc. and drying. This compn. is adapted for therapeutic uses.

"Face pack" composition. E. C. GOODE. U. S. 1,550,026, Aug. 18. A mixt. of K alum 2.5–3.5, casein 0.5–1.5 and oat-flour 18–22 parts is used with H_2O as a plastic pack for application to the skin to prevent or reduce wrinkles.

Tobacco. J. RAE. Brit. 231,355, June 16, 1924. Tobacco is "dressed" by treating it with steam "generated from an aq. soln. of KMnO_4 " in a rotating drum plated internally with Ni and provided with internal projections or spikes.

Apparatus for drying tobacco, etc. E. K. VIETOR. U. S. 1,555,779, Sept. 29.

Impregnating cut cigaret tobacco with an alcohol solution of menthol. L. F. HUGHES. U. S. 1,555,580, Sept. 29.

18—ACIDS, ALKALIES, SALTS AND SUNDRIES

FRED C. ZEISBERG

Synthetic ammonia: applications and manufacturing processes. F. LAMEY. *Bull. soc. ind. Mulhouse* 91, 410–31(1925).—Description and comparison of the Haber, Claude, Fauser and Casale processes. A. PAPINEAU-COÛTURE

Potash. J. W. TURRENTINE. *Mineral Ind.* 33, 591–9(1924).—A statistical review of production and trade. A. BUTTS

Should we have a potash industry? *Chem. Met. Eng.* 31, 14–5(1924).—What will potash cost the farmer? *Ibid* 31, 191–2. Future sources of potash and ammonia. *Ibid* 32, 284(1925). Potash readily obtainable from American sources. J. W. TURRENTINE. *Mfgs. Rec.* 87, 69–70; *Chem. Record Age* 23, 6–7(1925). E. J. C.

Sodium salts. A. G. WIKOFF. *Mineral Ind.* 33, 650–61(1924).—Discusses production of nitrate, NaCl, and other salts, with statistics. A. B.

Borax. T. R. LEIGHTON. *Mineral Ind.* 33, 6–9(1924).—A discussion of sources, production, and uses. A. B.

Magnesite. W. E. DORNBACH. *Mineral Ind.* 33, 460–71(1924).—Discusses classification, sources, production, trade and Mg metal, with a bibliography. A. B.

- Sulfur, pyrite and sulfuric acid.** A. E. WELLS. *Mineral Ind.* **33**, 662-74(1924).—Production, imports, uses and technology are reviewed. A. B.
- Antimony.** K. C. LI. *Mineral Ind.* **33**, 51-62(1924).—Discusses the shortage of Sb, also production in China and other countries and the Sb market. A. B.
- Arsenic.** V. C. HEIKES. *Mineral Ind.* **33**, 63-70(1924).—Supplies, production and prices are discussed. A. B.
- Barium and strontium.** ANON. *Mineral Ind.* **33**, 88-93(1924).—Sources and production of barytes and Ba and Sr chemicals are treated. A. B.
- Chromium.** W. D. JOHNSTON, JR. *Mineral Ind.* **33**, 119-28(1924).—Reviews technology, trade, production and prices of chromite and Cr chemicals. A. B.
- Selenium and tellurium.** S. SKOWRONSKI. *Mineral Ind.* **33**, 646-9(1924).—A review of uses and production, with bibliography. A. B.
- Iodine.** T. R. LEIGHTON. *Mineral Ind.* **33**, 100-1(1924).—Production in Chile and other countries, sources and uses are treated. A. B.
- Monazite.** S. J. JOHNSTONE. *Mineral Ind.* **33**, 501-5(1924).—Gives data on production, sources, trade and Th compds. A. B.
- Mica.** W. M. MYERS. *Mineral Ind.* **33**, 490-7(1924).—Classification and uses, production, market and imports and exports are discussed. A. B.
- Talc and soapstone.** R. B. LABOO. *Mineral Ind.* **33**, 675-80(1924).—A review of the industry, with statistics. A. B.
- Graphite.** BENJ. L. MILLER. *Mineral Ind.* **33**, 354-60(1924).—The industry in the United States and foreign countries is covered. A. B.
- Fluorspar.** H. W. DAVIS. *Mineral Ind.* **33**, 259-63(1924).—Covers production, consumption, imports and uses. A. B.
- Cryolite.** ANON. *Mineral Ind.* **33**, 254-5(1924).—Gives data on production and imports. A. B.
- Phosphate rock.** WM. H. WAGGAMAN. *Mineral Ind.* **33**, 559-73(1924).—Gives data of world production and notes on technology. A. B.
- Gypsum.** F. A. WILDER. *Mineral Ind.* **33**, 361-7(1924).—Statistics and discussion of production in the U. S. and other countries. A. B.
- Feldspar.** A. S. WATTS. *Mineral Ind.* **33**, 256-8(1924).—Statistics and discussion of production are given. A. B.
- Fuller's earth.** HERMAN GUNTER. *Mineral Ind.* **33**, 264-5(1924).—Data on production and imports are given. A. B.
- Asbestos.** OLIVER BOWLES. *Mineral Ind.* **33**, 71-80(1924).—An account of properties and uses, production and trade, with a bibliography. A. B.
- The new oxygen plant of the "Terres Rouge" Mining Co. at Belval.** MARCEL STEFFES. *Z. kompr. flussige Gase* **24**, 81-6, 97-100(1925).—Detailed description of a liquid-air fractionating plant employing the Linde process. R. I. DODGE
- The oxygen plant of the Siemens-Schuckert dynamo factory.** *Z. kompr. flussige Gase* **24**, 20-2(1925).—Description of a liquid-air fractionating plant using the Heylandt process. R. I. DODGE
- Silicate of soda as an adhesive.** REX FURNESS. *Ind. Chemist* **1**, 197-200(1925). cf. *C. A.* **17**, 326; **19**, 1018.—Variations in compn. and properties lead to many uses for Na silicates. Their solns. are used as adhesives in the manuf. of fiber board, veneers, asbestos products, abrasive wheels, and non-slip iron steps. WM. STERICKER
- The microscopical examination of chemical products. II.** C. H. BUTCHER. *Ind. Chemist* **1**, 381-2(1925); cf. *C. A.* **19**, 3181.—A comparison of gas black and lamp-black under the microscope is made. Carbon blacks giving a "short" ink can be easily and quickly distinguished from those giving a "long" ink. Long blacks can be converted into short blacks by treatment with steam at 500° and short blacks into long blacks by the introduction of some volatile impurity, such as tannin, in the form of a dil. alc. soln. two slides. E. G. R. ARDAGH
- Casein and its industrial applications.** F. C. C. LYNCH. *Can. Chem. Metallurgy* **9**, 203-5, 221-5(1925).—Attention is directed to the general uses of casein, the production, imports and exports of casein for Canada, the nature of the competition to be met and the general business conditions to be taken into account by the Canadian producer of casein. The natural sour or lactic acid process and the HCl or H₂SO₄ process are briefly outlined, while the renet method is set forth in some detail. Some attention is given to the economics of drying casein. A few of the more or less recent patents relating to the prepn. of casein are listed. The variations in casein, analyzed costs of manuf., transportation and selling fluctuations in prices, by-products, applications of casein in the paper industry, casein adhesives, casein plastics and casein paints are dealt with. List of patents. E. G. R. ARDAGH

A new process for the economical production of plastic materials from organic binding agents and powders, chiefly inorganic, insoluble in them. E. R. BESEMFELDER. *Chem.-Ztg.* 49, 747-8(1925).—The filling powder is treated with a current of an org., neutral, water-repelling fluid which does not decompose upon boiling, until every trace of moisture has been removed. The solvent is recovered in a condenser, and the dried powder is mixed intimately with the viscous org. binding agent, either alone or dissolved in some mobile org. liquid. Benzene, toluene, turpentine, CCl_4 and Cl-substituted hydrocarbons serve well in this process. W. C. EBAUGH

Carbonaceous material for absorption or catalysis (Brit. pat. 231,863) 21.

Sulfuric acid. H. PETERSEN. Brit. 231,853, April 1, 1924. Oxidation of SO_2 is effected by bringing the SO_2 into intimate contact with nitrosylsulfuric acid and other NO compds. dissolved in concd. H_2SO_4 , the oxidation being effected without liberation of gaseous N oxides. Kestner's atomizers, Schmiedel's rollers or Keller's sprayers may be used.

Sulfuric acid. G. F. HURT ENGINEERING CORPORATION. Brit. 231,921, Dec. 11, 1923. In the manuf. of H_2SO_4 by the nitration process, interaction between the liquids and gases is obtained by projecting the liquids into the progressing gases in successive fountains of drops which are of sufficient size that they are not carried away by the gas stream. An app. and details of operation are described. Cf. C. A. 19, 563.

Sulfuric acid. LODGE-COTTRELL, LTD. Brit. 231,536, March 31, 1924. The roaster gases cooled during elec. purification from dust and As are reheated to the proper temp. before admission to the chambers, by the heat evolved in a denitrating device.

Arsenic acid. C. G. RICHARDSON. U. S. 1,554,371, Sept. 22. Na arsenate or other sol. arsenate is treated with $\text{Fe}_2(\text{SO}_4)_3$ and the resulting insol. arsenate is then treated with H_2SO_4 to produce arsenic acid.

Drum for transporting hydrofluoric acid. R. M. MEIKLEJOHN. U. S. 1,553,321, Sept. 15. Metal barrels or drums which are preferably formed of steel are provided with an inner "passification crust" by filling the drum to about 90% its capacity with HF of about 58% strength and allowing it to stand for about 48 hrs. at a temp. of about 27° and then for 7 hrs. at about 60° while atm. pressure is maintained by means of a ventilating bung.

Ammonia; carbon monoxide; hydrocyanic acid. NORSK HYDROELEKTRISK KVAELSTOFAKTIESELSKAB. Brit. 231,134, March 21, 1924. The H_2O required for the production of NH_3 and CO by the catalytic decomp. of HCN present in gases which also contain H is produced *in situ* at an elevated temp. by introducing a gas contg. O. If air is used, the process may be combined with HCN manuf., the gases, after absorption of NH_3 and addn. of hydrocarbons or carbonaceous material being blown through an *elc.* arc. H may be added, if present in insufficient amt. in the original gases used. Cf. C. A. 19, 2392.

Ammonia synthesis. L. CASALI. Brit. 231,417, March 29, 1924. Reaction gases for catalytic NH_3 synthesis are purified by a preliminary treatment with NH_3 (preferably that from a previous catalysis) in excess of the amt. required to form solid compds. with C oxides, H_2S , NO and acid compds. present.

Nitrogen for ammonia synthesis, etc. COMPAGNIE DE PRODUITS CHIMIQUES ET ELECTROMETALLURGIQUES ALAIS, FROGES, ET CAMARGUE. Brit. 232,185, April 14, 1924. A mixt. of N and H free from O and suitable for NH_3 synthesis is obtained from products of combustion with slight excess of air of coke-oven gas, "lighting gas," "poor gas" or similar gases. Excess O is removed by treatment with H at high temp. and CO_2 may be absorbed in NH_3 soln.

Cyanides of the alkali metals. P. COMMENT and D. HATT. U. S. 1,555,944, Oct. 6. Ca cyanamide, CaC_2 and alkali metal carbonate, e. g., Na_2CO_3 , are heated together in equimol. proportions to produce a substantially quant. yield of NaCN (or other cyanide). A temp. of about 500° may be employed.

Alkali aluminates. K. FLOR, T. LICHTENBERGER and SALZWERK HEILBRONN AER.-GES. Brit. 231,147, March 19, 1924. A mixt. of alkali metal chloride, e. g., NaCl and Al_2O_3 , in the resp. mol. proportions of 6 to 1, is treated with steam at 500 – 600° , forming a porous aluminate and HCl. A salt of Mn, Cu, Cr or Mg may be added as a catalyst. The aluminate may be decomposed with CO_2 to produce alkali carbonate and Al_2O_3 and the latter used to react with more alkali chloride.

Ammonium sulfate. SOC. DES FOURS A COKE SEMET SOLVAY ET PIETTE, SOC.

ANON. Brit. 231,788, Dec. 30, 1924. Crude NH_4 sulfate crystals, after draining, are washed with successive satd. solns. of NH_4 sulfate, each of greater degree of purity than that previously used. The excess of washing liquor (after employment in cyclic succession) is returned to the saturator and the crystals are given a final washing with NH_4 sulfate soln. preferably rendered alk. by addn. of NH_3 , or of NH_4 carbonate or bicarbonate. An app. is described.

Aluminium sulfate. H. WRIGLEY. Brit. 230,916, Dec. 19, 1923. Aluminous materials such as shales, fireclays or blaes which do not disintegrate during leaching are leached as a mixt. of fines and coarser material. The soln. obtained is submitted to a settling process at $55-65^\circ \text{Tw.}$ and the clear liquid is concd. and crystd.

Sodium perborate. DEUTSCHE GOLD UND SILBER SCHEIDEANSTALT VORM. ROESSLER AND O. LIEBKNECHT. Brit. 231,945, Jan. 11, 1924. CO_2 is passed into a reaction mixt. of Na peroxide, H_2O and H_3BO_3 or alkali borates so as to leave a Na_2CO_3 soln. contg. some NaHCO_3 . To the mother liquor, more Na peroxide and H_3BO_3 or borate is added and NaHCO_3 also may be added. Silicates, phenols, etc., may be added as stabilizing agents.

Basic lead sulfate. B. S. WHITE. U. S. 1,555,538, Sept. 29. By-products recovered in the smelting of Pb ores or similar materials and contg. a large proportion of basic Pb sulfate are projected in finely divided form into a highly heated furnace which is simultaneously supplied with SO_2 and air to produce a basic Pb sulfate of the desired degree of basicity.

Recovery of cadmium as sulfate. M. F. COOLBAUGH and J. B. READ. U. S. 1,552,595, Sept. 8. Materials such as flue dusts which contain both As and Cd are roasted with H_2SO_4 and Fe_2O_3 or other ferric compds. to produce CdSO_4 and a ferric arsenate from which the CdSO_4 may be readily leached with H_2O .

Recovery of cadmium as sulfate. J. B. READ and M. F. COOLBAUGH. U. S. 1,552,506, Sept. 8. Flue dust or similar material contg. both As and Cd is roasted with Fe pyrites and H_2SO_4 or other Fe-contg. sulfate-forming material to produce CdSO_4 .

Recovering fluorspar, etc., from waste dumps. G. M. JACKSON and CLAY CROSS CO., LTD. Brit. 231,575, Jan. 1, 1924. Mech. features of fluorspar, etc., recovery from waste dumps of Pb mines or similar wastes.

Potassium values from residues of molasses fermentation or other organic waste materials. H. A. NIBECKER. U. S. 1,555,512, Sept. 29. Fermentation or sugar extrn. residues or other similar org. waste materials are reduced to ash form by slowly conveying them through an enlarged passage in contact with a heated gaseous medium such as combustion gases to dry them and then initiating and propagating combustion of the dried material in a passage of smaller diam. U. S. 1,555,513 relates to a rotary kiln adapted for use in this process.

Separating calcined colmanite from clay, etc. H. D. HELLMERS. U. S. 1,556,110, Oct. 6. Centrifugal action, baffling and suction are employed. An app. is described.

Quick-setting hydrated lime containing aluminium fluoride. M. E. HOLMES and G. J. FINK. U. S. 1,554,183, Sept. 15.

Quick-setting hydrated lime containing zeolites. M. E. HOLMES and G. J. FINK. U. S. 1,554,184, Sept. 15.

Fixing nitrogen. J. C. CLANCY. U. S. 1,550,202, Oct. 6. A counter current flow of molten Na_2CO_3 and air and natural gas or other gas contg. both N and hydrocarbon is maintained through a fixed porous catalytic mass comprising nitrides of Ta, Cr, Th, Ti and Mn, to produce cyanide.

Hydrogen. BADISCHE ANILIN & SODA FABRIK. Brit. 231,218, Nov. 26, 1923. H or a mixt. of H and N (adapted for making synthetic NH_3) is produced by igniting hydrocarbons in the gaseous phase with O or air (both being preferably preheated), then oxidizing the CO in the product to CO_2 by steam in the presence of a catalyst such as Fe oxide and finally removing the CO_2 . Coke-oven gas may be used as a starting material.

Hydrogen and oxygen from water. SYNTHETIC AMMONIA AND NITRATES, LTD. Brit. 232,431, May 29, 1924. H_2O is decomposed by the action of Hg which may be used in vapor form with H_2O vapor. The Hg oxide formed is regenerated in a cyclic operation.

Apparatus for producing hydrogen by the iron-steam process. COMPAGNIE DE PRODUITS CHIMIQUES ET ELECTROMETALLURGIQUES ALAIS, FROGES, ET CAMARGUE. Brit. 232,184, April 11, 1924.

Colloidal sulfur. C. C. LOOMIS and H. E. STUMP. U. S. 1,549,886, Aug. 18. Rosin soap or other colloid is added to a soln. of an alkali metal polysulfide or other

polysulfide of a non-volatile base, the soln. is acidified, *e. g.*, with gaseous SO_2 , and the pptd. S is recovered by filtering and washing.

"Free-burning" sulfur. J. W. SCHWAB. U. S. 1,556,037, Oct. 6. Aniline, diphenylamine or other org. compd. sol. in molten S is added to the latter to improve its burning properties. The S may contain oil as an impurity.

Decolorizing carbon. L. L. HAMON and ARTIFICIAL COAL CO. (HANON PROCESS), LTD. Brit. 231,935, Jan. 9, 1924. The H_2O content of peat, lignite, sawdust or similar material is reduced to 25–35%, and after grinding and treatment with $\text{Ca}(\text{OH})_2$ to facilitate disintegration, the material is carbonized and treated with steam, CO_2 , H or Cl and then with hot acidulated H_2O .

Decolorizing carbon. H. MÜLLER-CLEMM and GES. FÜR CHEMISCHE PRODUKTION. Brit. 218,628, July 5, 1923. The process of Brit. 216,130 (*C. A.* 19, 156) for prepg. decolorizing C by carbonizing a mixt. of sulfite cellulose soln. or similar material and alkali sulfides with or without alkali carbonate is modified by the introduction of CO_2 to form carbonate in the soln. The ppt. is removed and the soln. then evapd. to dryness and carbonized. $\text{Ca}(\text{OH})_2$ is added to sulfite cellulose soln. and the filtered ppt. is leached with hot K sulfide soln., the Ca pptd. with CO_2 and the soln. treated as before.

Decolorizing carbon. H. M. SHILSTONE. U. S. 1,556,039, Oct. 6. Fibrous rice material such as hulls, straw or chaff is partially burned to a charred mass and then treated with alkali, *e. g.*, with NaOH soln., to produce a porous material and leave a product free from resinous substances.

Argon and lead oxide. P. E. HAYNES. U. S. 1,555,570, Sept. 29. A gaseous mixt. contg. O and A in proportions greater than in atm. air is brought into contact with Pb maintained at a temp. above its m. p.

Shaped articles of metal oxides. N. B. PILLING. U. S. 1,553,394, Sept. 15. Filaments for thermionic devices or other articles are shaped from metals such as Ni with a Ca coating and then slowly oxidized in dry O.

Hardening gelatin or other colloids. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit. 231,564, Dec. 10, 1923. Gelatin or other colloid is successively mixed with or treated with non-hardening agents which together exert a hardening action; *e. g.*, dichromate may be used in conjunction with ferrous NH_4 sulfate, hydroquinone, or Na formaldehyde-sulfoxylate, or formaldehyde bisulfite may be used with alkali.

Catalysts. BENZONAFTENE. Brit. 231,458, March 26, 1924. Na formate is added to catalytic materials such as Fe, Ce or Th oxides, reduced Fe or Ni or other "heavy" or "rare" metals having a m. p. above 550° , in order that, when heated, the nascent H produced from the formate may further activate the catalyst.

Catalysts. A. T. LARSON. U. S. 1,555,505, Sept. 29. A composite promoter comprising an oxide of Zr and an oxide of a relatively basic element such as K_2O is used with catalysts such as Fe oxide in the manuf. of NH_3 from N and H.

Fused oxide catalysts. A. T. LARSON. U. S. 1,554,008, Sept. 15. In making a fused oxide catalyst, adapted for NH_3 synthesis, a bed of material such as Fe oxide from which the catalyst is to be formed is heated by electrodes to fuse a portion of the material.

Absorbents for gases. GES. FÜR CHEMISCHE PRODUKTION. Brit. 231,466, March 25, 1924. Gases or vapors are absorbed by active charcoal obtained by carbonization in the presence of alk. salts such as K_2CO_3 , K sulfide or K polysulfide and are recovered after absorption by distn. *in vacuo* or with steam. The charcoal may be prepd. as described in Brit. 216,130 (*C. A.* 19, 156) and Brit. 218,628 which specifies modifying the process of Brit. 216,130 (especially in using sulfite cellulose lye) by introducing the carbonate in the form of CO_2 , which may, *e. g.*, be passed into a mixt. of sulfite cellulose lye and K sulfide, the ppt. being sepd. by filtration and the filtrate evapd. to dryness and carbonized.

Using chemical reagents on porous carriers. AKT.-GES. FÜR CHEMIEWERTE. Brit. 231,901, April 5, 1924. Acids or other reagents for nitration, sulfonation, oil purification and other reactions are mixed with a porous substance such as bone black, fuller's earth or burnt kieselguhr. *E. g.*, PhNO_2 may be made by treating C_6H_6 on the water bath with HNO_3 absorbed in kieselguhr. Numerous other examples are given.

Polishing glass. W. TAYLOR, F. W. PRESTON and KAPPELLA, LTD. Brit. 230,882, Oct. 18, 1923. A mixt. of resin or pitch with a smaller quantity of beeswax, Japan wax or carnauba wax is used for satg. felt, cloth or other fibrous material for polishing glass.

Cleaning lenses. C. H. OHLWILER. U. S. 1,556,248, Oct. 6. Blocking compd. such as that formed from pitch is removed from lenses by a solvent bath of heavy coal tar distillate, the residue of this solvent is removed by an acid bath, *e. g.*, H_2SO_4 , and the lenses are freed of the acid bath by washing with H_2O .

Composition for dispersing rain drops on glass, etc. O. HEIDEMANN and M. JOHN. U. S. 1,555,852, Oct. 6. A mixt. of clay, H_2O and soda.

Metal polishes. H. A. SCRIVEN and B. F. G. GUISSA. Brit. 232,034, April 11, 1924. Tripoli powder 1.5 oz. is mixed with gasoline 1 pint and oil of mirbane 1 dram.

Cleaning aluminium. P. P. BAILEY and E. M. BAILEY. U. S. 1,554,483, Sept. 22. Al is placed in a soln. contg. an oxalate, acetate or a similar compd. of an org. acid and sugar, starch, gums or other carbohydrate-supplying material, boiled in the soln., removed and washed.

Detergent for cleaning aluminium ware. M. M. WILSON. Brit. 231,987, Feb. 26, 1924. Citric acid or acid Ca citrate is mixed with pumice, with or without $CaCO_3$.

Polishes for leather, linoleum, wood, etc. J. SCHWARZKOPF. Brit. 231,774, July 8, 1924. Coffee wax (a wax-like material extd. from coffee or coffee husks and obtained in the manuf. of caffeine-free coffee) is used to the extent of $1/2$ -3% together with other waxy materials, dyes, etc.

Mixture for cleaning and polishing wood, metal or other surfaces. M. OKAMURO. U. S. 1,555,149, Sept. 29. Furfural 2 qts., gasoline 2 qts., "ammonia" 0.1 gal., carbolic acid 2 oz., vinegar 1 gal., soap 6 lbs. and H_2O $1\frac{1}{2}$ gals.

Polish for furniture, automobiles, etc. B. H. WRIGHT. U. S. 1,550,137, Aug. 18. Bofax, 1 oz., is mixed with wax 4 oz., oil 2 pints and H_2O 3 qts.

Backing for stencil sheets. H. E. SMITH. U. S. 1,550,330, Aug. 18. Stencil sheets are backed with sheets of manila jute paper or other flexible material carrying a H_2O -repelling coating which may comprise varnish or shellac and an overlying coating of yielding and preservative material such as paraffin.

Mixture for cleaning straw hats. C. POSLUSZNY. U. S. 1,550,044, Aug. 18. Powd. chalk 0.24, oxalic acid 0.94, SO_2 47, Pb acetate 0.47, "salts of lemons" 0.24, Na hyposulfite 0.94 and H_2O 96.7 parts.

Packing mixture. M. P. EBBESEN. Brit. 231,154, March 18, 1924. See Danish 33,931 (C. A. 19, 1477).

Packing for reaction towers. H. W. SCHAFER. Brit. 231,199, March 24, 1924. Fillers for absorption, reaction or distg. towers are formed of spirals of sheet metal or rolled wire.

Electrostatic and mechanical separation of asbestos from non-fibrous gang. G. H. HORNE. U. S. 1,549,875, Aug. 18.

Phenol aldehyde condensation product. G. W. MILES. U. S. 1,549,888, Aug. 18. Condensation is effected in the presence of $SnCl_2$ which serves to initiate a vigorous reaction such that cooling is preferably employed.

Plastic composition. W. HOSKINS. U. S. 1,556,115, Oct. 6. A phosphatic material such as bone ash or phosphate rock is admixed with H_2SO_4 and an aluminate binder, e. g., Na or Ca aluminate to form a compn. suitable for molding.

Plastic compositions. WESTERN ELECTRIC CO., LTD. Brit. 231,781, Nov. 28, 1924. Fused silica is degasified (for use as a filler in plastic compns. of the kind described in Brit. 182,422 (C. A. 16, 4308)) by heating it for at least an hr. to a temp. slightly below its sintering point, e. g., to about 900-1000°.

Plastic composition adapted for making molded boxes, etc. C. JAEGER. U. S. 1,553,820, Sept. 15. A compn. adapted for molding under heat and pressure comprises sawdust 80, straw waste 20, coal ashes 50, corn starch 10-15, Fe chloride 10, H_2O 20, rosin 2 and lithopone $1/2$ part.

Separating constituents of fibrous thermoplastic mixtures. H. P. SHOPNECK. U. S. 1,555,763, Sept. 29. Mixts. such as those contg. fibers and rosin or bitumen from box toe stock are disintegrated in the presence of H_2O to render the binder suspendable in the H_2O so that it can be sepd. from the fibrous material. After its sepn. it is heated to facilitate its sepn. from the associated H_2O .

Casein compositions. W. H. SIMMONS and BRITISH XYLONITE CO., LTD. Brit. 232,071, March. 15, 1924. In forming plastic compns., a small proportion of an aq. emulsion of rubber or latex is added to the casein which is then worked up in the usual way.

Moldable compositions. G. PETROFF. Brit. 231,431, March 25, 1924. Oxycellulose (with or without gypsum or other substances) together with an acid catalyst is added to the liquid reaction product obtained by warming phenol and formaldehyde together without a catalyst, and the mixt. is molded and heated to harden the products.

Molded fiber articles. C. C. LOOMIS and H. E. STUMP. U. S. 1,552,625, Sept. 8. Wood, leather or other fiber is treated with natural latex, partially coagulated, e. g. by HOAc or alum, and then molded.

Forming molded receptacles or other products from pulps. H. BUEL. U. S. 1,549,903, Aug. 18. A fluent pulp is forced under superatm. pressure against a foraminous mold wall and an inert gas such as N, neon or CO₂ is forced under pressure to deposit the materials remaining suspended in the supply conduit after the supply has been cut off. A further supply of heated inert gas serves to dry the material in molded form.

Shoe lasts of molded material. E. L. AIKEN. U. S. 1,550,232, Aug. 18. A rough shape of paper pulp is formed in a mold, the H₂O is dried out, and it is then impregnated with a liquid binder such as a "carboloid" compn. capable of undergoing a chem. change which will render it semi-flexible at normal room temp. The mass is then pressed to semi-finished shape, heated to produce the desired change in the binder, machined to size, coated with "carboloid" and polished.

Mat surfaces on transparent material. C. E. SWERT. U. S. 1,549,814, Aug. 18. A soln. of CaCl₂ is applied to "window envelopes" or other transparent material and, on evapn., leaves a deposit giving a mat surface.

Lining metal pipes. B. TALBOT. U. S. 1,555,257, Sept. 29. A fluid mixt. of hydrocarbon material and powdery reinforcing material, e. g., a mixt. of pitch and granite chippings, is applied as a lining to pipe which is rapidly rotated until the lining mixt. has set.

Acoustic diaphragms. F. A. E. JENKINS. Brit. 232,394, March 24, 1924. See U. S. 1,511,166 (C. A. 18, 3689)

Firelighters. S. SAMSOG. Brit. 231,829, April 7, 1924. Cardboard, sawdust, paraffin, charcoal and KClO₃ are specified.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

The manufacture of semi-opaque glasses. H. V. RENN. *Ind. Chemist* 1, 383-5 (1925). Opacification results from colloidal sepn. in a glass due to the introduction of such substances as oxides of Sn, Zn, Al, Ti, Zr, Sb and As, Cu₃(PO₄)₂, BaCO₃, asbestos, china clay, feldspar, cryolite, fluor spar, fluosilicates, and salts such as sulfates, chlorides and bromides. Generally compds. contg. Al are used in conjunction with fluorides and fluosilicates. "Opalescent" glass is transformed to "alabaster" glass when sufficient chlorides and sulfates have been added to increase the size of the suspended particles until white light is transmitted. Various ways in which opacification can be brought about or regained are described and the quantities of the substances used are given.

E. G. R. ARDAGH

The viscosity and allotropy of glass. HENRY LECHATELIER. *Ann. phys.* 3, 5-21 (1925).—See C. A. 19, 2114.

R. H. LOMBARD

Thermotechnical investigations of glass furnaces. I. Heat flow in a Siemens-step-grate generator. G. GEHLHAFF, O. RICKLEFS AND W. SCHREIBER. *Z. tech. Physik* 6, 278-87 (1925). The thermal efficiency of an open, step-grate Siemens generator, using coarse lignite, referred to its upper heating value is about 65%. In the heat balance, Langbein's formula ($H = 85 C + 270 H + 25 S - 25.5 O$) together with the elementary analysis of the fuel is used to det. calorific value. **II. The gasification of lignite in a Siemens-step-grate generator.** *Ibid.* 338-51.—Numerous measurements of the temp. and numerous gas analyses at different depths of the charge of a Siemens-step-grate generator have been made. The analysis of the lignite used together with other data lead to diagrammatic representations of the temp. distribution and the distribution of CO and CO₂ in the generator for different operating conditions. The following balances have been made on the operations: CO₂; air-N₂; S; H₂O-H₂; O₂ and heat balances.

J. H. PERRY

The preparation of coppered glass mirrors. E. A. H. FRENCH. *Trans. Optical Soc. (London)* 25, 229 (1924); *J. Soc. Glass Tech.* 9, No. 33, 34-5.—The phenylhydrazine method of Chattaway (C. A. 2, 1517) for prep. Cu mirrors from aq. solns. of Cu salts was found by F. to give satisfactory results only on interior curved surfaces. Plane surfaces could not be coated satisfactorily because of contamination with the tarry by-products formed. Better results were obtained with hydrazine sulfate. In the method finally adopted, the glass to be coppered was fastened to the under side of a Cu float capable of suffering rotation in the coating bath, which in its turn was kept at the desired temp. by a hot water bath. The glass was cleaned with concd. HNO₃, washed,

immersed for 1 hr. in 1% KOH soln., washed well first with tap and then with distd. water. The surface was then polished with a clean dry cloth, quite grease-free, and the glass fixed to the float. The coating bath was made up as follows: 9 g. of hydrazine sulfate were dissolved in 150 cc. of distd. water and heated at 60°, and to this was added, with const. stirring, 90 cc. of a satd. soln. of Cu hydroxide and NH_3 at 16°, the resulting mixt. being a clear yellow color. The glass was then sponged over with the mixt., this being a most necessary step in the process. To the soln. was then immediately added slowly and with const. stirring 87.5 cc. of a soln. at 60° of 11.1 g. of pure KOH in 100 cc. of water. The solns. should still be of a yellow color without any pptn. taking place. The mixt. was then poured into the coating vat (of Cu) standing in the hot water bath at 43°, and the glass on the float at once immersed and the float periodically rotated. The temp. of the bath was then very gradually raised to 57° over a period of about 20 min. for the first 15 of which the bath turned a dark green color before finally acquiring a pink shade. After a further 5 min. the film was thickened by the addn. of a mixt. of 50 cc. of the Cu hydroxide- NH_3 soln. at 16° with 10 cc. of the KOH at 60°, the temp. of the bath being dropped to 43° before the addn. The float was removed during the addn. and stirring of the mixt., and was quickly replaced and the same heating schedule followed. Further reinforcements of the coat could be obtained by repetitions of the above, and by electroplating from a bath made by boiling 1 part of K bitartrate with 10 parts by weight of water and adding as much hydrated Cu carbonate as would dissolve. A safe c. d. was 0.25 amp./sq. dm. heavier currents tending to cause stripping of the film. The ordinary acid or cyanide plating baths were no good. The process was appreciably cheaper and safer than that using phenylhydrazine.

H. G.

Segregation (of ceramic materials) in bins. T. W. GARVE. *J. Am. Ceram. Soc.* **8**, 666-70(1925).

C. H. KERR

Talc as the principal body ingredient in vitrified ceramic bodies. H. M. KRANER AND S. J. McDOWELL. *J. Am. Ceram. Soc.* **8**, 626-35(1925).—"The prospect of bonding talcs with clay and firing the resulting compns. to vitrification is a doubtful possibility" except under very close temp. control. Compns. lying in the forsterite field seem more promising. The presence or addns. of small amts. of various RO constituents helps to lengthen the firing range.

C. H. KERR

The chemical and physical properties of fire clays from various producing districts. M. C. BOOZE. *J. Am. Ceram. Soc.* **8**, 655-65(1925).—Chem. analyses, fusion points and firing characteristics of a number of flint and plastic clays from various districts are given and uses discussed.

C. H. KERR

The mechanical, thermal and optical properties of fused silica. ELIHU THOMSON. *J. Franklin Inst.* **200**, 313-26(1925).—Clear fused silica can now be made in large masses reasonably free from bubbles by melting in a vacuum furnace and subjecting the fused mass to a high pressure during cooling. At 1750° SiO_2 begins to sublime rapidly. It has no m. p. Fused silica is like glass, hard, brittle, but more elastic and more transparent to ultra-violet and infra-red light as well as to the visible spectrum. Coeff of expansion is very low; at 200° it is 518×10^{-9} and changes very little up to 1000°. The n_D is 1.459. It is non-hygroscopic and is a good elec. insulator. Slow cooling or holding too long at about 1200° will cause crystal. and loss of its unique properties.

R. J. MONTGOMERY

Testing silica bricks. E. STEINHOFF. *Stahl u. Eisen* **44**, 1277-83(1924).—The methods of testing silica bricks at the Research Institute of the Dortmund Union are described with reference to 3 samples. The tests employed include a complete analysis, detn. of the m. p., true and apparent sp. gr., porosity, crushing strength at high temps., permanent expansion after prolonged heating, and percentage transformation of the quartzite into cristobalite and tridymite; the macrostructure and microstructure are also examd. The best bricks contain a min. of 95% SiO_2 , and m., 1710-1730°, and have a true sp. gr. of about 2.35. The sp. gr. decreases after heating for prolonged periods at 1500-1600° to this value even when the brick as delivered has a higher sp. gr., while the porosity also decreases. A well-fired brick will withstand a crushing strain of 3.5 kg. per sq. cm. up to over 1550°, and should become stronger with continual use at temps. about 1500°; after 24 hrs. at this temp. no further changes in length should take place, and in any case the increase in length after this firing should not exceed 2-3%. Photomicrographs are included to show the characteristic changes that take place in the microstructure after varying periods of firing.

B. C. A.

An X-ray study of cyanite and andalusite. J. T. NORTON. *J. Am. Ceram. Soc.* **8**, 636-9(1925).—Examn. by the X-ray diffraction method showed structures of cyanite and andalusite different from one another and from sillimanite. Upon heating, the

compsds. are converted into another form which gives the diffraction pattern of mullite or sillimanite. C. H. KERR

Differentiation between mullite and sillimanite by their X-ray diffraction patterns. L. NAVIAS AND W. P. DAVEY. *J. Am. Ceram. Soc.* 8, 640-7(1925).—The X-ray diffraction patterns of pure sillimanite and pure mullite are shown to be different. By X-ray methods it is shown that the cryst. component of calcined clays is mullite, not sillimanite, a conclusion in agreement with chem. and optical data found in the literature but not in accord with the negative results previously reported by several workers in X-ray crystallography. C. H. KERR

Some features of tank block comparisons. F. S. THOMPSON AND H. I. VORMELKER. *J. Am. Ceram. Soc.* 8, 611-7(1925).—Life of tank blocks is increased by lower furnace temps. obtained by increasing the area of melting chamber and by insulation of the walls. Analyses and phys. tests of clays and blocks are given; results of service tests are also given but "data do not warrant conclusions." C. H. KERR

The quantitative determination of iron existing as ferrosilicon in artificial corundum. R. A. HEINDL. *J. Am. Ceram. Soc.* 8, 671-6(1925).—Det. the total Fe by the combined acid treatment and KHSO_4 fusion. Det. the amt. of ferric oxide present by the fusion method with KHSO_4 . Subtract the Fe as ferric oxide from the total Fe and the difference is Fe present as ferrosilicon. Grains of artificial corundum examd. showed 0.070-0.171% Fe as ferrosilicon. The coarser grains contain more and the finer, less. C. H. KERR

The relation of structure and composition to thermal efficiency of refractories when used in regenerators. S. M. PHELPS. *J. Am. Ceram. Soc.* 8, 648-54(1925).—Lowering the porosity of checker brick increases thermal efficiency by reason of greater heat capacity, which is a function of wt. and sp. heat. Glazing a clay brick does not materially impair its efficiency, because the greater part of the heat leaves the surface of the brick by convection and this is affected only by the surface area, which is not changed by glazing. SiC is of little value for checkers because of its low thermal capacity. C. H. KERR

Abrasives. ANON. *Mineral Ind.*, 33, 1-10(1924).—A review of natural and artificial abrasives, with statistics. A. B.

Enameling defects due to cast iron. A. I. KRYNITSKY. *J. Am. Ceram. Soc.* 8, 618-22(1925).—Discussion of the effect of the amt. and condition of the C. C. H. KERR

Gas-fired enameling furnaces without muffles. H. H. CLARK. *J. Am. Ceram. Soc.* 8, 623-5(1925). C. H. KERR

Compressibility of several glasses (BRIDGMAN) 2. Qualities of firebrick (GRUM-GRZHIMAILO) 9. The stability relations of modifications in the polymorphous system, Al_2SiO_5 (NEUMANN) 2. Metal pins, etc., for joining artificial teeth or other ceramic materials (U. S. pat. 1,555,315) 9.

Glass-refining furnace. A. GRAUEL. U. S. 1,552,555, Sept. 8.

Glass-melting furnace. B. H. SCHIELDROP. U. S. 1,554,251, Sept. 22.

Pot for melting glass. H. SCHNITRPFEIL. U. S. 1,552,884, Sept. 8.

Annealing glass. J. BENNETT. U. S. 1,553,283, Sept. 8. Glass is annealed in a closed chamber from which air and gases are withdrawn to effect cooling in a partial vacuum.

Furnace for annealing glass. F. W. KNOWLES and KILNER BROS., LTD. Brit. 231,975, Jan. 31, 1924.

Vertical leer for annealing glassware. R. GOOD. U. S. 1,554,275, Sept. 22.

Ceramic articles. E. ANDERSON. U. S. 1,556,193, Oct. 6. In making ceramic articles such as emery wheels the materials are puddled and mixed with a temporary binding substance such as linseed oil, enclosed in a mold and heated in an oven sufficiently to cause the binding substance to unite the constituents of the mixt. This heating is continued until the puddle is dry, the puddle being subjected indirectly to air currents in the oven.

Kiln and mode of operation for salt glazing ceramic ware. C. DRESSLER. U. S. 1,556,208, Oct. 6.

Earthenware. H. OEXMANN. Brit. 231,469, March 27, 1924. In making earthenware, clay or the like is subjected to high pressure, e. g., 300 atm., either as a mass or in the form of shaped articles. The pressure may be exerted through a gaseous, liquid or powd. medium and to avoid penetration of the liquid the body may be coated with rubber or shellac soln. or treated with oil, fat or ceresite. Gypsum and cement articles may be similarly treated.

Silica-lime brick. C. MENDIUS. U. S. 1,554,639, Sept. 22. Granulated blast-furnace slag is mixed with a small proportion of lime and of granite, flint or other hard crushed material of high silica content, moistened and molded under high pressure and then cured for several hrs. with steam at high pressure.

Electric furnace adapted for firing fine pottery, etc. C. A. CADWELL. U. S. 1,555,401, Sept. 29.

Refractory brick. W. CROW and J. C. SCHAFFER. U. S. 1,553,143, Sept. 8. A refractory material adapted for use in paving or firebrick or in lining furnaces is prepd. by heating dolomitic limestone 86, clay 10, Fe ore 3 and orthoclase 1 part.

Refractory material. J. W. MARDEN and H. K. RICHARDSON. U. S. 1,554,225, Sept. 22. A layer of Th oxide is applied to the surface of fireclay bricks or other refractory materials to improve their resistance to high temps. The Th oxide may be mixed with ZrO_2 and double fluorides and H_2O to facilitate its application to the material as a coating. Cf. C. A. 19, 3359.

Refractory materials for repairing furnaces, etc. B. C. SELLARS. Brit. 231,650, March 11, 1924. Na silicate is dried and mixed with a refractory material such as Al_2O_3 , asbestos, gannister, or barytes and the mixt. is prepd. for use by addn. of H_2O .

Refractory cement. P. J. F. KESTNER. Brit. 231,141, March 21, 1924. A mixt. of bauxite 1-40 and aluminous cement 2 parts, with or without a refractory aggregate, is used for making and repairing furnaces, bricks, etc.

Bonded abrasive articles. P. JOHANSON and C. B. TILTON. U. S. 1,555,119, Sept. 29. Granulated corundum, Si carbide or other abrasive material is bonded with dry Na silicate and Na silicate in liquid form, and caused to set by heating without fusion. The silicate used constitutes over 10% of the total mixt.

Bonded abrasive articles. C. B. TILTON and M. F. BEECHER. U. S. 1,535,086, Sept. 29. Grains of emery, corundum, Si carbide or other abrasive material are mixed with dry Na silicate and with gum tragacanth or other temporary viscous binder, molded and heated to 850-1000°.

Binder for use with abrasives. H. R. POWER. U. S. 1,553,105, Sept. 8. A cement mixt. contg. $Ca(OH)_2$ and which may include port. cement is treated with CO_2 to convert the $Ca(OH)_2$ into $CaCO_3$ and produce a dense homogeneous product after being molded with admixed abrasives.

• **Oven or furnace adapted for heating enameled articles.** H. B. CANNON. U. S. 1,550,340, Aug. 18.

Enameling both sides of flat metal articles, etc., in tunnel kilns. C. DRESSLER. U. S. 1,552,475, Sept. 8. Mech. features.

Kiln for enameling ware. C. A. HAHN. U. S. 1,549,830, Aug. 18

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Cement. R. W. LESLEY. *Mineral Ind.* 33, 104-18(1924).—Production, prices, stocks, trade, technology and the foreign cement industry are reviewed. A. B.

Effect of the sulfide content on the properties of blast-furnace slags and cements. R. GRÜN. *Stahl u. Eisen* 45, 344-6(1925).—The m. pts. and the microscopical and hydraulic properties of fused mixts. contg. slags, both natural and synthetic, together with increasing proportions of CaS, were detd. A comparative series of tests substituting CaO and MgO for CaS, was also carried out. The results showed that a fairly high sulfide content is not injurious to cements; on the contrary, it increases the strength and does not induce rapid setting, as is often assumed. When present in small quantity, the CaS forms an eutectic with the silicates, is taken up by them into solid soln. at higher temps., and, on cooling, seps out in dendritic form. When present in large amt., it seps out in globular form. B. C. A.

Ground water corrosion of concrete. H. BRATKE. *Wasser u. Gas* 15, 444-6(1925).—B. reports the action of a ground water on an underground concrete structure. The high sulfate content of the water in contact with the concrete suggested the failure might be due to the formation of Ca Al sulfates. B. warns against placing concrete under ground without an examn. of the ground strata and the ground water. M. E. F.

Paving compositions having a rubber base for modern roads. ARNAUD. *Rev. gén. caoutchouc* 1925, No. 14, 12-4.—A description of the principal types of paving materials developed by de Caudenberg, viz., rubberized asphalt, elastic cement and colloidal macadam, all of which have been patented (cf. C. A. 16, 629; 17, 3787). C. C. D.

Report of Committee 4. Preservatives. L. C. DREFAHL, *et al.* *Proc. Am. Wood-Preservers' Assoc.* 1925, 47-77.—Data including service records and tests are presented for wood-tar creosote, low-temp. tar and 10 proprietary compds. including Aczol and Wolman Salts. A toxicity study of petroleum samples (gas oil fraction) from 42 sources shows that none was sufficiently toxic to be used alone as a wood preservative. A revision of the float test of residue in creosote is presented for adoption as standard. The Comm. proposes the substitution of a new flask with short neck and side tubulature for the retort now standard for creosote distillation. The standard methods for the volumetric and gravimetric analysis of ZnCl_2 are combined and slightly revised. No recommendation is made with reference to standard specifications and methods of analysis of petroleum for admixt. with creosote but chem. and phys. data are given of such mixts.

ALFRED L. KAMMERER

Report of Committee 5. Treatment. E. H. HORROCKS, *et al.* *Proc. Am. Wood-Preservers' Assoc.* 1925, 122-215.—Specifications for the treatment of the following classes of materials are presented: fir ties, piling, posts and cedar poles. The treatment of car material is discussed but no specifications are presented.

A. L. K.

Report of Committee XVII. Wood preservation, Appendix A. Revision of manual. HERMANN VON SCHRENK, *et al.* *Proc. Am. Ry. Eng. Assoc.* 1925, 65-75.—The Assoc.'s standard float test of residue remaining in the retort after distn is revised as to perfection of app. and method of procedure. A specification for a thermometer, 0° to 400° , is presented for adoption as standard for use in creosote distn. Standard methods for the analysis of ZnCl_2 , a volumetric one based on titration with K ferrocyanide with acetate as an external indicator and a gravimetric method based on the pptn. as sulfide in a weak H_2SO_4 soln. and ignition to ZnO are also presented. The Comm. suggests as a substitution for the glass retort now standard for creosote distn. a short-necked flask of the same capacity with a side tubulature. Such a flask is easier to obtain true to specified dimensions and it is claimed that it will yield results concurrent with those of the retort.

ALFRED L. KAMMERER

Report of Committee XVII. Wood preservation, Appendix B. Service test records. C. F. FORD, *et al.* *Proc. Am. Ry. Eng. Assoc.* 1925, 76-101.—Six additional completed service test records of treated ties are reported. A table is included showing the renewals per mile (1900-1923) for 20 railroads. *Fence post test.*—In 1913 the A. T. & S. F. Ry. started a test at Cleveland, Texas, with several hundred pine fence posts treated with various preservatives. 21 posts were pressure treated with 2% and 4.5% ZnCl_2 absorbing 1.3 and 0.5 lb. per cu. ft. Seventeen were creosoted by the full-cell and 22 by the empty-cell processes with retentions of 3.4 and 5 lb., resp. Additional posts were painted with coal-tar creosote, carbolineum, wood-tar creosote and certain proprietary compds. Others were treated with Na_2SiF_6 and antinonin in an open tank. After 3 yrs. the untreated controls were badly decayed as were most of the painted posts, also those treated with antinonin. The Na_2SiF_6 posts showed decay after 3 yrs. and were badly decayed after 11 yrs. The posts treated by pressure with creosote and ZnCl_2 were in excellent condition after 11 yrs. except 1 ZnCl_2 post which showed decay after 7 yrs. Posts treated with 0.35 to 0.48 lb. FeCl_2 and with 0.89 CuSO_4 per cu. ft. in 1918 had practically failed after 6 yrs.

A. L. K.

Report of Committee XVII. Wood preservation, Appendix C. Treatment with a mixture of creosote and petroleum. R. S. BELCHER, *et al.* *Proc. Am. Ry. Eng. Assoc.* 1925, 102-11.—Creosote for mixts. with petroleum may be any of the standard grades. Creosote-coal-tar solns may be used with certain kinds of petroleum. The petroleum should preferably be of asphalt base but an oil of mixed paraffin and asphalt may be used if when mixed with creosote not more than 1% sediment is formed. The sp. gr. of the petroleum is not important. It must have a min. flash p. in a closed test. of 225°F . The viscosity of the mixt. must be such that it will readily penetrate the wood. Petroleum adds to the life of the timber by retarding checking and splitting. A creosote-petroleum mixt. complying with the above conditions and contg. sufficient creosote to prevent decay is an economical and satisfactory preservative in many regions.

ALFRED L. KAMMERER

Report of Committee XVII. Wood preservation, Appendix F. The effect of preservatives on the inflammability of wood. E. H. BOWSER, *et al.* *Proc. Am. Ry. Eng. Assoc.* 1925, 113-29.—A discussion of the inflammability of creosoted pine particularly as used in bridge and trestle structures. Except with freshly treated material the fire hazard in using creosoted timbers is no greater than if as great as that of untreated wood.

ALFRED L. KAMMERER

Quantity of wood treated and preservatives used in the United States in 1923.

R. K. HELPHENSTINE, JR. *Proc. Am. Wood-Preservers' Assoc.* 1925, 297-321.—A very complete statistical summary, compiled in coöperation with the U. S. Forest Service. ALFRED L. KAMMERER

Wood preservation in Europe. C. M. TAYLOR. *Proc. Am. Wood-Preservers' Assoc.* 1925, 179-189.—A report on observations made while on an European trip. ALFRED L. KAMMERER

A theory on the mechanism of the protection of wood by preservatives. VI. Toxic principles of creosote. ERNEST BATEMAN AND C. HENNINGSEN. *Proc. Am. Wood-Preservers' Assoc.* 1925, 22-8; cf. *C. A.* 14, 1063; 16, 628, 4041; 18, 2064; 19, 2870.—Exptl. data are presented from which the following conclusions are drawn: (1) The essential toxic materials in coal-tar creosote are the hydrocarbon oils b' below 270° and the tar acids and bases b. above 270°. (2) The hydrocarbons distg. below 270° are so much more toxic that they may be considered the essential toxic materials of creosote. (3) The high-boiling tar acids and tar bases may be considered the essential toxic materials for high-boiling distillates such as carbolineum, the potentially toxic hydrocarbons being too insol. to be effective. ALFRED L. KAMMERER

Determining the penetration of metallic salts in treated wood by means of Röntgen rays. F. MOIL. *Z. angew. Chem.* 38, 592(1925) cf. *C. A.* 19, 1185.—Sections of fir and spruce (5 to 20 mm.) untreated and treated with HgCl_2 and NaF were exposed to Röntgen rays over photographic plates. The heart and sap wood as well as the spring and summer wood are distinctly differentiated on the plates. NaF shows no image even in highest concns., whereas HgCl_2 shows a distinct demarcation between the treated and untreated regions. Sections of telegraph poles treated with HgCl_2 and NaF tested in the same manner showed no penetration beyond the limits indicated by the usual $(\text{NH}_4)_2\text{S}$ stain test applied to adjacent sections (cf. *C. A.* 19, 1185), proving that the latter test is entirely satisfactory. ALFRED L. KAMMERER

A one-movement process for impregnating timber with zinc chloride and petroleum. A. M. HOWALD. *Proc. Am. Wood-Preservers' Assoc.* 1925, 81-101.—A process has been developed at the Mellon Institute in coöperation with the Grasselli Chem. Co. for the treatment of timber with an emulsion of ZnCl_2 and petroleum. The water-in-oil emulsion contains 15 to 25% of a 10 to 40% ZnCl_2 soln., the natural asphaltum constituents of a suitable fuel oil acting as a stabilizer. The usual procedures for pressure impregnation are employed. The emulsion is maintained in a state of agitation during treatment by means of a circulating pump. The temp. should not exceed 180° F. The penetration obtained with oak, pine and gum is satisfactory and shows a selective absorption of ZnCl_2 . Operating cost data are presented. ALFRED L. KAMMERER

The comparative resistance of eighteen species of wood-destroying fungi to zinc chloride. C. A. RICHARDS. *Proc. Am. Wood-Preservers' Assoc.* 1925, 18-22.—A series of toxicity tests parallel to the series reported in 1924 (*C. A.* 19, 2871), ZnCl_2 being substituted for NaF. The order of resistance of the fungi to the 2 salts is very different. NaF is slightly more toxic than ZnCl_2 to $2/3$ of the fungi tested. A. L. K.

Methods of prolonging life of mine timber. G. M. HUNT. *Bur. Mines, Bull.* 235, 73-110(1925).—A general discussion of the economics of wood preservation as applied to mine props, including a description of the methods of preliminary handling, peeling, seasoning and preservative treatments with creosote, ZnCl_2 , NaF and CuSO_4 by pressure and non-pressure processes. Specifications for creosote and ZnCl_2 are presented as well as service records of treated timbers in mines, also a consideration of cost on basis of annual charge. A selected bibliography is appended. A. L. K.

When is rot not rot? W. H. LONG. *Proc. Am. Wood-Preservers' Assoc.* 1925, 202-15.—An investigation was initiated to det. whether ties showing incipient decay before treatment are sterilized by the preservative treatment as practiced at a railroad treating plant. The woods studied were Douglas fir, Engleman spruce and cork-bark fir from the mountains of New Mexico, western yellow pine and Texas pine. The ties were treated by the Rueping Process with a 45-55 mixt. of creosote and petroleum at a temp. of approx. 180° F. The timber was affected by the following wood-destroying fungi: *Tremetes pini*, *Polyperus ellisianus*, *P. Schweinitzii*, *Lenzites sepiaria* and *Lenzites lepidus*. The high altitude species were thoroughly sterilized as was the bulk of the Texas pine ties. The sterilization of the western yellow pine was not so successful. ALFRED L. KAMMERER

Temperature and moisture changes in wood under steaming treatment. R. M. WIRKA. *Proc. Am. Wood-Preservers' Assoc.* 1925, 271-289.—A continuation of a former study (cf. *C. A.* 19, 2871). As the work is still unfinished no recommendations are made for steaming practice in timber treatment. ALFRED L. KAMMERER

Nitro-5-chloro-2-hydroxytoluene (for preserving wood) (Brit. pat. 230,968) 10.
Refractory brick (U. S. pat. 1,553,143) 19.

Cement. A. GAERTNER. Brit. 231,007, April 11, 1924. A finely powd. mixt. of fuel and materials which react with the ash to form cement is injected upwardly into the furnace of a Bettington boiler or other vertical cylindrical furnace in which the fuel burns with a mushroom-shaped flame.

Cement. SOC. ANON. DES CEMENTS FRANCAIS AND BUREAU D'ORGANISATION ECONOMIQUE. Brit. 232,155, April 9, 1924. Cement-forming materials are fed to a rotary kiln, pass first through a zone at a temp. of about 1000°, then to a zone at 1600–1700° and are discharged in a molten state above 1500°.

Portland cement. H. KÖHL. Brit. 231,535, March 31, 1924. A cement having high initial strength without excessive speed of setting comprises, preferably, SiO₂ 14–18, Al₂O₃ 6–10, Fe₂O₃ 5–10, and CaO 60–65%. Generator slag, blast furnace slag, siliceous bauxites, pyrites cinders and siliceous Fe ores may be used as raw materials.

Cement containing titanium. E. C. ECKEL. U. S. 1,555,405, Sept. 29. An artificial Ti compd. such as a slag contg. Ti is added to a cement mixt., during or before fusion or clinkering, to produce a quick-hardening cement resistant to chem. action and of high sp. gr.

Aluminous cement. S. SEAILLES and J. SEAILLES. U. S. 1,556,038, Oct. 6. After placing in position a layer of aluminous cement, a layer of ordinary cement is immediately placed over it.

Aluminous cement construction. SOC. LAP. Brit. 231,867, April 1, 1924. A layer of aluminous cement or concrete, after being formed but before it sets, is faced or backed with another layer of ordinary hydraulic cement and the 2 layers are allowed to set together simultaneously.

Compositions of cements and synthetic resins. V. LEFEBURE. Brit. 231,242, Dec. 29, 1923. Port. cement or other cements or plaster compns. are mixed with condensation products such as those of phenol-, urea-, or thiourea-formaldehyde and the mixt. is molded and heated to effect conversion of the condensation product into final form after setting of the cement. The condensation product may be preliminarily adsorbed by or mixed with a filler such as kieselguhr or colloidal clay.

Cement clinker. C. B. HILLHOUSE. U. S. 1,555,283, Sept. 29. Lime is added to Fe sponge in less quantity than that required for clinker, the materials are fused in a fusion furnace at a temp. substantially lower than that for clinkering, liquid slag is withdrawn from the furnace, heated to clinkering temp. and admixed with a further quantity of lime to form cement clinker.

Rotary cement kiln. J. W. FULLER. Brit. 231,139, March 19, 1924.

Charging rotary cement kilns, etc. A. ANKER. Brit. 231,875, April 2, 1924. In feeding a cement-forming mixt. or the like to a rotary kiln, the material is passed by an extrusion press through a heated tube whence it goes into the kiln in broken pieces of approx. even size free from dust and small fragments.

Impregnating concrete. F. S. HONBERGER. U. S. 1,555,208, Sept. 29. Air and moisture are exhausted from concrete by the action of a vacuum, the concrete is heated and is submerged in a hot impregnating liquid such as asphalt while still *in vacuo*. The material is then cooled and subjected to pressure to facilitate impregnation.

Composition for waterproofing concrete. F. GUY. U. S. 1,550,355, Aug. 18. A soapy soln. is mixed with sand, allowed to set, pulverized and mixed with alum.

Impregnating concrete. F. S. HONBERGER. U. S. 1,555,209, Sept. 29. Concrete piles or other articles of concrete or similar porous material are submerged in heated asphalt or other impregnating material and allowed to become heated and subsequently to cool in the liquid, meanwhile circulating the liquid and removing foam which is formed.

Light-weight aggregate for use in concrete. G. A. WALKLEY. U. S. 1,556,268, Oct. 6. A plastic mixt. is formed of clay and finely divided coal or other fuel, molded masses are formed from this mixt. and they are dried and fired in a kiln.

"Artificial marble." H. J. KIMMEL and L. A. HARRIS. U. S. 1,550,077, Aug. 18. A mortar of pasty consistency and which may be formed of MgO, marble dust or sand, port. cement, asbestos, MgCl₂, MgSO₄ and CaCl₂ is allowed to dry in forms at a temp. of about 27° for about 24 hrs., and then, after removal of the forms, is maintained at about 35° for a period of about 24 hrs. The temp. is then increased to about 52° during a period of about 36 hrs.

Building material. A. C. FISCHER. U. S. 1,550,310, Aug. 18. Sheets of tar paper,

felt or similar material are satd. with a slow-drying adhesive substance such as gilsonite and vegetable oils which forms an adhesive surface.

Building blocks, roofing tiles, etc. H. GRONROOS. U. S. 1,552,431, Sept. 8. Molded articles for building purposes are formed by mixing slags 400, glass refuse 100, clay 100, Fe oxide 1, KNO_3 5 and quartz 2 parts, adding H_2O , molding under a pressure of 50–200 kg. per sq. cm., and burning first at about 300° for about a half hr. and then at about 740° for a half hr.

Waterproof building material. F. T. WALKER. Brit. 231,653, March 13, 1924. Ground oolitic limestone is mixed with pitch and tar, with or without bitumen or a small addn. of cement. The mixt. may be molded into blocks or applied directly in building construction.

Bituminous compositions. R. C. VAN HAAGEN. Brit. 231,503, March 27, 1924. A compn. for covering roads, roofs, floors, etc., comprises a soln. of vulcanized rubber in asphalt mixed with a mineral filler such as sand, pulverized basalt or slag.

Coating composition. N. E. NEWMAN. Brit. 217,542, June 14, 1923. A coating compn. adapted for use on roofs, basement walls, etc., comprises long fiber blue or yellow asbestos (known as amosite and mined in Griqualand, South Africa) and a binder, preferably of elastic material such as Trinidad or Bermuda asphalt or gilsonite. Drying oils also may be added.

Composition shingles. W. H. GRAVEMAN. U. S. 1,549,867, Aug. 18. Shingles, etc., are formed by heating a mixt. of pulverized coal taf pitch and pulverized slag or similar material to about 100° , pressing the heated mixt. into the desired shape and then heating to a carbonizing temp.

Dyed waterproof floor-covering felt impregnated with wax tailings. L. KIRSCHBRAUN. U. S. 1,549,991, Aug. 18.

Apparatus for forming felted waterproofed sheets. L. KIRSCHBRAUN. U. S. 1,549,992, Aug. 18.

Heat-insulating building board composition. D. C. LOHMANN. U. S. 1,554,358, Sept. 22. Paper pulp 50–60, clay 25–75 and wheat flour 2–12 lbs.

Preserving wood. A. C. HOLZAPFEL. Brit. 231,029, May 6, 1924. Hot wood is treated with a soln. of oleate of Hg, Zn or Cu or a similar compd. in gasoline, with or without the addn. of rubber or coumarone resin.

21 FUELS, GAS, TAR AND COKE

A. C. FIELDNER

The evaluation of coal. KARL STOCKFISCH. *Z. angew. Chem.* **38**, 611 (1925), cf. C. A. **19**, 1485.—The amt. of air needed for combustion is about 1.5 times that calcd. from an elementary analysis. The net heating value can only be approximated from analysis. C. G. KING

Froth flotation of Indian coals. W. R. NDALL. *Records Geol. Survey India* **56**, part 3, 220–249 (1925).—The advisability of using the froth flotation process for cleaning Indian coals is discussed. The advantages and disadvantages are brought out and the equipment needed is described. The results of flotation tests on 35 coals are given. Ten analyses of typical coals are recorded. A bibliography is included. J. F. S.

The drying of brown coal through gases. HILLIGER. *Die Wärme* **48**, 273 (1925).—The use of air and furnace gas for the drying of brown coal is dealt with and their efficiency is demonstrated by means of diagrams. OSCAR PAUK

Manufacture of some by-products of coal distillation. A. BARIL. *Extrait compte rend. 41ème congrès soc. tech. ind. gaz. France* **1924**, 1–41. A detailed description of the processes used at the Gennevilliers plant of the Société d'Éclairage, Chauffage et Force Motrice (Paris) for the extn. of crude phenols from coal tar and for the manu. of H_2SO_4 , and of the control of $(\text{NH}_4)_2\text{SO}_4$ manu. A. PAPINEAU-COUTURE

The distillation of coal and tar with the use of a metal bath. A. THAU. *Glückauf* **61**, 821–31 (1925). OSCAR PAUK

Coal and coke. R. W. MORRIS. *Mineral Ind.* **33**, 129–63 (1924).—Production, stocks, consumption, imports and exports, and the industry in foreign countries are covered. A. B.

The combination of water in deep swamp mold. GUSTAV KEPPELER AND FRIEDRICH KRANZ. *Kolloid-Z.*, Special No., Apr. 1, 1925, p. 318–29.—Water in peat can be free (drains out), pressed out (capillary according to Ostwald), adsorbed H_2O (colloid H_2O according to Ostwald), and chemically bound H_2O . Since the drying of peat

the most important problem in its prepn., the amt. of H_2O in each condition is an important consideration. A vapor pressure-concn. diagram seems the best way to study the condition of the H_2O in peat. An old sphagnum peat was prepd. in as pure a form as possible, frozen, drained, pressed, air-dried, heated at 100° and heated at 230° . Unchanged peat contains 85% H_2O after draining, 75–80% after pressing, 18% after air drying and takes up 43% when rewet. Frozen peat contains 84% H_2O after draining, 70% after pressing, 15% after air drying and takes up 40% when rewet. Peat heated to 100° contains 83% H_2O after draining, 70% after pressing, 8% after air drying and takes up 33% when rewet. Peat heated to 230° contains 61% H_2O after draining, 50% after pressing, 2.5% after air drying and takes up 10% when rewet. When vapor pressure is plotted against % of H_2O there are sharp breaks in the curves which appear at the points indicated by the data above. F. E. BROWN

Vacuum distillation and steam distillation in the production of benzene. H. BÄHR AND G. RÜHL. *Glückauf* 61, 574–80 (1925).—The advantages of the distillation of benzene in vacuum against steam distillation are as follows: The lower consumption of steam, the possibility of a just as complete sepn. of the washing oil and the better saving of the latter. OSCAR PAUK

Second report of the marine oil-engine trials committee. G. G. GOODWIN, *et al.* *Proc. Inst. Mech. Eng* 1925, 439–532; discussion 542–605.—An extremely detailed account of stationary tests ashore and of steady speed and maneuvering tests afloat. The engines were 2-cycle with mech. fuel injection and an extensive heat recovery system. The ship in which the sea tests were performed was of 11,533 tons displacement. WM. B. PLUMMER

- **Gaseous combustion at high pressures. V. The explosion of hydrogen-air and carbon monoxide-air mixtures at varying initial pressures up to 175 atmospheres.** WM. A. BONE, D. M. NEWITT, AND D. T. A. TOWNSEND. *Proc. Roy. Soc. (London)* 108A, 393–418 (1925), cf. C. A. 18, 2069.—By the use of a Cr-Ni steel bomb with spherical explosion capacity of 239 cc., and tested to withstand 2000 atm. pressure, gaseous explosion tests were made with H-air and CO-air mixt., with initial pressures ranging up to 175 atm. H, O, N, CO and A were used as diluent gases. The time for reaching max. pressure was within 0.005 sec. and decreased with increasing P_i , except for the CO-air mixt., in which case it increased 8 times from $P_i = 3$ atm. to $P_i = 175$ atm. The difference is attributed to N_2 activation (I). Secondary formation of NO was negligible except when an excess of air was present. In that case NO_2 was formed (2–2.4%) in excess of the theoretical amt., which was also attributed to (I). There was no evidence of "after burning" when P_i exceeded 10 atm. The amt. of steam dissociated never exceeded 1%. Dissociation of CO_2 (15–25%) could be almost entirely suppressed by using an excess of CO, even at 3000° . The corrected P_m/P_i ratio increased in every case with increasing P_i , 14.3–31.8% for a P_i range of 3–150 atm. C. G. KING

(Producer) gas cooling with recovery of heat. JULIUS FABIAN. *Z. angew. Chem.* 38, 185–7 (1925).—Producer gas from coke is usually hot enough to use under waste-heat boilers. Brown-coal gas is not only much cooler, but heavily loaded with H_2O vapor. F. proposes to cool brown-coal producer gas by H_2O sprays. The gas passed up through a packed tower down which cold H_2O is sprayed. The heated H_2O goes to a 2nd packed tower up through which the blast for the producer is passed. The H_2O from here goes to a spray-pond to be further cooled before returning to the first tower. This cools the gas, lowers its H_2O content (thereby increasing its flame temp.) and not only returns the heat to the producer but furnishes enough H_2O vapor in the hot moist blast to replace all the steam previously supplied from boilers. Applied to a producer gasifying 220 tons per day of raw brown coal of 55% H_2O , the air blast was heated to 52° and satd. at that temp., replacing 22 tons per day of boiler steam. On a producer gasifying 100 tons per day of brown coal briquets of 15% H_2O , 88% of the steam needed (26.5 tons) was returned. W. L. BADGER

The importance of the production of tar and its derivatives in the national economy of Italy. LUIGI DAL PRATO. *Rass. min. met. chim.* 63, 42–5 (1925); cf. C. A. 19, 3156. Methods for converting tar into other com. products by various processes are described, including its distn. at ordinary pressure in the presence of porous catalytic substances with and without a gas current and the catalytic depolymerization of heavy oil with and without the aid of reducing gases under pressure. C. C. DAVIS

Stream pollution by wastes from by-product coke ovens. R. D. LEITCH. U. S. *Pub. Health Repts.* 40, 2021–6 (1925).—A review and discussion, mentioning particularly the bacterial filter, benzene washing, and coke quenching as the most important methods for removal or destruction of phenol in plant effluents. Although the latter process produces corrosive gases and increases plant maintenance costs, it seems to be the best

available, at least for plants producing metallurgical coke in which the presence of odor is not deleterious. A bibliography of 87 references is given. WM. B. PLUMMER

Low-temperature distillation and the central station. G. A. ORROK. *Elec. World* 86, 620-2 (1925).—Because of the mech. and thermal difficulties in low-temp. coking, its application by central stations would be of doubtful value. They use but 6% of the bituminous coal consumed. It is claimed that it is not economical to save by-products when coal costs more than \$1.50 per ton (909 kg.) and the by-products bring less than \$1.62 per ton. W. H. BOYNTON

Gas washing (WEISSENBERG) (WEISSENBERG, SCHUSTER) 13. Combustion control of open hearths (CONWAY) 9. Experiments with explosive gas mixtures (OHMANN) 2. Explosion experiments with vaporized liquids (OHMANN) 2. Petroleum and natural gas (DAY) 22. Coal washing in 1924 (RICHARDS, LOCKE) 9. Distilling lignite (Brit. pat. 231,453) 22. Retort for distillation of coal (U. S. pat. 1,552,471) 1. Distilling tars (Brit. pat. 231,686) 13. Emulsions for binding fuels (U. S. pat. 1,556,005) 22.

Fuel for internal-combustion engines. H. TERRISSE. U. S. 1,556,047, Oct. 6. Kerosene or other hydrocarbon material heavier than ordinary gasoline is mixed with EtOH and AcH. Cf. *C. A.* 19, 166

Lignite fuel. E. P. SCHUCH. U. S. 1,556,036, Oct. 6. Lumps of raw dehydrated lignite are impregnated with oil.

Carbonaceous material for fuel, absorption or catalysis. F. GOUTAL and H. HENNEBUTTE. Brit. 231,863, April 1, 1924. Wood, peat or lignite is charred at a temp. below 500° and mixed with a binder such as oxidized substances from the heat treatment of tar from wood, peat or lignite, which are decomposable at temps. below 500°, with or without a small quantity of oxides or salts of Cu, Ni, Zn or Fe. The mixt. is pulverized, compressed and heated at 300–500° until evolution of H₂O vapor ceases.

Liquid motor fuel. H. B. HUTCHINSON and DISTILLERS CO., LTD. Brit. 232,276, Oct. 17, 1923. A stable mixt. of alc. and gasoline is obtained by distg. the mixt. until the greater portion of the contained H₂O has passed over, allowing the distillate to stand, and mixing the layer consisting mainly of alc. and hydrocarbon with the mixt. of alc. and hydrocarbon remaining in the still.

Non-freezing motor-cooling composition. J. R. CLAWSON. U. S. 1,550,009, Aug. 18. A mixt. of potato flour or similar starchy material, tannin, CaCl₂ and H₂O.

Briquetting fuel. L. LIAIS. Brit. 231,140, March 18, 1924. Asphaltic material m. 90–120° is melted and treated with 2½–5% of NaHCO₃ or other substance capable of forming gas within the mass to convert it into a foam, which is rapidly cooled, e. g., by running into cold H₂O. The resulting porous mass is crushed and mixed with coal dust for briquetting.

Fuel briquets. W. PRESCOTT and D. F. WORGER. U. S. 1,554,462, Sept. 22. Small coal 90% or more is mixed with less than 0.25% of lime, 1% of glue and 6% of H₂O and there is added to the mixt. a 40% CH₂O soln. in the proportion of not more than 0.20%, immediately before pressing and molding.

Charcoal fuel briquets. W. A. LEUBENBERGER and W. T. DUMBLETON. U. S. 1,550,034, Aug. 18. Briquets molded from previously prepd. charcoal are heated to 115–315° according to the characteristics of the product desired.

Apparatus for preparing fuel from peat. E. P. R. ULMANN. U. S. 1,554,472, Sept. 22.

Apparatus with steam-jacketted tubular retorts for distillation of carbonaceous fuels, shale, etc. F. LAMPLOUGH. U. S. 1,554,587, Sept. 22.

Treating coal. J. F. LAHART. U. S. 1,555,590, Sept. 29. Coal is treated with about 1–2% of a mixt. of salt, lime and cement, to regulate its combustion and lessen the smoke production.

Carbonizing coal. W. RUNGE. Brit. 231,159, March 21, 1924. Pulverized coal or other carbonaceous material is carbonized by showering it through a rising stream of hot combustible gases, the volatile products being withdrawn together with the hot gases at the upper part of the carbonizing zone, which is maintained at a temp. not exceeding about 815°. An app. is described.

Carbonization of coal or other fuels. H. E. SMITH. Brit. 231,298, Feb. 28, 1924. Finely divided fuel is charged into spherical containers which are heated by passage through a heated chamber in a gas producer or gas producer plant.

Distillation of coal, peat, etc. F. M. PERKIN and BETTISFIELD TRUST CO., LTD. Brit. 232,358, Jan. 31, 1924. Coal, peat or other material to be distd. or carbonized in externally heated retorts in which inert gas or steam is passed through the charge is

preheated to about 250° before introduction into the retort. This avoids clogging of the retort in the case of bituminous coal. An app. is described.

Drying and distilling peat. H. NIELSEN. Brit. 231,592, Jan. 5, 1924. Pulped or macerated peat is heated, subjected to the action of a vacuum filter, treated with superheated steam under pressure and then subjected to a sudden release of pressure in an expansion chamber. It may then be briquetted, further dried and distilled to produce coke, oils, NH_3 and gas.

Rotary drum apparatus for distilling coal, etc. KOHLENSCHIEDUNGS-Ges. Brit. 232,456, July 11, 1924.

Apparatus for producing combustible gas from water and crude oil or other liquid hydrocarbons. E. M. C. McALPINE. U. S. 1,550,273, Aug. 18.

Water gas. HUMPHREYS AND GLASGOW, LTD. Brit. 231,866, April 3, 1924. During the blow, air passes downwards through a superheater, up a carburetor and thence to a producer where it flows upwards and downwards to 2 different valves. Other features of control of flow of gases and steam are described. Cf. C. A. 18, 2422.

Down-run apparatus for water-gas manufacture. P. DVORKOVITZ. U. S. 1,554,073, Sept. 15.

Gas producer. RHEINISCHE METALLWAAREN- UND MASCHINEN-FABRIK and F. PACHER. Brit. 232,496, Sept. 19, 1924. An auxiliary air blast app. is provided which supplies air on reduction in pressure due to failure of the main air supply.

Gas purifying apparatus. H. LUMB, J. E. HORSFALL and R. DEMPSTER & SONS, LTD. Brit. 232,012, March 17, 1924.

Gas retort furnace construction. H. J. TOOGOOD and R. DEMPSTER & SONS, LTD. Brit. 232,357, Jan. 31, 1924.

Coking fuel briquets. T. A. GOSKAR. Brit. 231,934, Jan. 9, 1924. Fuel briquets for coking comprise a mixt. contg. 70–90% of a non-caking coal and 30–10% of a binder formed by grinding caking coal to a powder of 150–200 mesh and adding H_2O tar, etc., to form a smooth paste. The coking of the briquets may be effected with hot producer gas.

Coking pitch or other bituminous materials. F. W. SPERR, JR. U. S. 1,553,641, Sept. 15. Pitch or similar material is treated with hot kerosene or other solvent to extract the more readily fusible constituents and the residue is then coked.

Coke oven. P. ALIDJIADIS. U. S. 1,553,795, Sept. 15.

Coke-oven construction. J. BECKER. Brit. 232,173, April 10, 1924.

Coke oven with vertical heating flues. SOC. GENERALE DE FOURS A COKE SYSTEME LECOQ. Brit. 231,483, March 29, 1924.

Coking-retort oven. J. BECKER. U. S. 1,553,662, Sept. 15.

22- PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

F. M. ROGERS

Chemical transformations of petroleum. HENRY GAULT. *Bull. soc. ind. Mulhouse* 91, 439–66(1925).—An address on cracking, hydrogenation, chlorination and oxidation of petroleum.

Petroleum and natural gas. D. T. DAY. *Mineral Ind.* 33, 515–58(1924).—A review of the industry, covering U. S. and world production, supplies and petroleum shale.

The bituminous schists of Castoreale and Barcellona (Sicily). M. BAKUNIN and F. GIORDANI. *Ann. chim. applicata* 15, 265–72(1925).—The zones of schist occur in Eocene clay superposed on cryst. rock and are composed chiefly of very thin strata, though a certain proportion occurs in strata several cm. thick. The following data give percentages for a thick sample of schist and the limiting percentages of 10 other samples of thin schists: H_2O 1.33, 2.06–5.77; volatile 10.63, 11.23–22.80; fixed C 6.51, 5.95–11.67; ash 81.53, 61.83–77.19; total S 2.14, av. 2.20; total N 1.60, av. 1.78. The data indicate that the schists are not inferior to Scotch schists (cf. Alderson, C. A. 14, 3526). The best results were obtained by distg. at 500–50° in a closed retort, under which conditions the thick and thin schists gave the following results: pyrobitumen (fixed C + volatile) 17.14, 17.18–33.11; oil distd. 8.8, 5.6–11.0; aq. NH_3 4.0, 6.0–9.0; oil from the pyrobitumen 52, 28–33; fixed C in the coke —, 7.0–11.0. The % oil from the bitumen indicates that the thick and thin schists differ in character. The thick schist and a typical thin one yielded 28.66 and 37.20 m.³ of gas (0° at 760 mm.) per

ton, which contained unsatd. hydrocarbons, CO_2 , O, CO, CH_4 , H and N and had calorific powers of 5650 and 6394, resp. The distd. oil combined from all the schists had d. 0.960, calorific power 10,783 and S 2.62% (cf. Giordani, *C. A.* 19, 2740), which indicates a good quality because of the low S content. The schists are in general promising because of the good yields of oil and N and their low S content. C. C. DAVIS

A new furnace for the distillation of bituminous schists. F. GIORDANI. *Ann. chim. applicata* 15, 273-82(1925).—A description, with diagrams and photographs, of a new type of furnace which differs from the Messel and Scotch types (cf. Scheithauer, *Die Schwelteere*, 2nd Ed. Leipzig 1922) in that a thermal balance is established in the furnace based on the fact that kerogen decomps. in 2 stages (cf. MacKee and Lyder, *C. A.* 15, 3904; De Bartolomeis, *L'industria del gas e degli acquedotti* 8, 158(1919)) and that the heat of decompn. is very small (cf. Masse, *Le Gaz*, ii, 754, Paris 1914; MacKee and Lyder, *C. A.* 15, 3905; Jones, *C. A.* 16, 1500). The general principles of the Scotch process were followed, except that external heat was replaced by internal heating with gas from combustion of the coke. In this way there was the enormous advantage of eliminating cond. through the walls and through a material of very low thermal cond. The best results were obtained at 500-50° higher temps. being attained at the expense of the oil. The vertical furnace comprises 3 zones, increasing in size from top to bottom. The schist is charged at the top and is preheated in the upper zone, from which lead tubes for withdrawing gas and vapors. The main distn. occurs in this upper zone and the coke descends at 500-50° to the next zone and meets an ascending air current. In this zone combustion of the fixed C occurs at 700-50°. The air which enters through tuyères in the lower zone recovers the heat of the descending residue. This lower zone is immersed in a H_2O -seal, and the H_2O , which requires a temp. of 70-80°, vaporized, is entrained by the air current and is carried through the combustion zone, the yield of NH_3 (cf. Franks, *C. A.* 15, 939) and the heat efficiency being thus increased. A condenser, gas extractor and scrubber, centrifugal fan, etc., complete the equipment. The yield of oil is 80-85% that in a closed retort on a lab. scale. Four furnaces each 7 m. high and with zones increasing from 0.5×0.5 to 0.8×0.8 m. distg. a total of 10 tons per day are in successful operation. C. C. DAVIS

Italian standard methods for mineral oils, colors and boiled oil. *Z. deut. Öl-Fett-Ind.* 45, 477-8, 494-5(1925).—Standard methods proposed by the Italian Commission under the following captions: Benzine and fuel oils. I. A. Phys. detns. B. Chem. detns. II. Benzine and petroleum. III. Fuel oils. Lubricating oils. 1. Cylinder oils. 2. Motor and steam-turbine oils. 3. Steamer oils. 4. Compressor oils. 5. Axle greases. 6. Machine oils. 7. Refrigerator oils. P. ESCHER

Detection and elimination of odors from oil refineries. R. S. WESTON. *Proc. Am. Soc. Civil Eng.* 51, 1193-7(1925); cf. *C. A.* 19, 2124.—A discussion. J. M. H.

Transformer oils and methods of testing them. I. MUSATTI AND A. PICCHETTO. *Ann. chim. applicata* 15, 238-65(1925).—A detailed and crit. discussion of the so-called German, French, Italian, English, Brown-Boveri and Snyder methods and the tentative Am. Soc. Testing Materials procedure for detg. the tendency of transformer oils to form a sludge. All these methods have shortcomings and none duplicates the conditions under which sludge is formed in actual use. Expts. were carried out with a view to detg. the relation between the phys. and chem. properties of oils from different sources and their tendency to oxidize. The oxidation expts. were based on a method which differed in detail from any of those above, but which most closely resembled the Brown-Boveri method. Cylindrical Cu cups, 50.3 mm. diam. and 63 mm. high and marked at a depth of 50.3 mm., allowed the reception of 100 cc. of oil. These were heated with free access of air both in a const. temp. air oven and in an oil bath at different temps. for long periods. After oxidation the oil was let stand, dild. with 2 vols. of benzine or preferably petr. ether, and centrifuged or let stand, filtered, washed on a tared filter and dried at 105°. An aliquot part of the filtrate was tested for acidity (by extn. with EtOH) after evapn. of the solvent *in vacuo*. The sludge, though insol. in benzine and petr. ether, was sol. in CHCl_3 , CCl_4 , C_6H_6 and partially in AmOH and EtOH + Et $_2\text{O}$, contained asphaltenes and was similar in all respects to the sludge formed under normal conditions in the same oil. Furthermore the sludge was identical in part with substances originally present in mineral oils and which, therefore, have originated in an analogous manner. The results indicate that there is no relation between the I no., Br no. or formolite no. of the original oil and its tendency to oxidize under the conditions of the expts. On the other hand the greater the proportion of an oil extractable with liquid SO_2 , i. e., the greater the amt. of non-satd. or aromatic hydrocarbons, the greater is the quantity of sludge obtained. Even at relatively low temps. such as 93° the amt. of sludge formed on exposure to air for such periods as 800 hrs. may be considerable and at higher temps. the amt. increases

rapidly, an approx. parallelism existing between the temp. and the proportion of sludge formed (cf. Snyder, *Proc. Am. Soc. Testing Materials* 24, ii, 955(1924)). A bibliography of 66 references is included. C. C. DAVIS

The breakdown mechanism of moist insulating oil. A. GYEMANT. *Naturwissenschaften* 13, 726-7(1925).—Small water drops, emulsified in oil, tend to assume an ellipsoid form when brought in a strong elec. field with $\alpha = f(rE_0/\gamma)$; α is ratio between major axis and diam. ($2r$) of original sphere, E_0 is field intensity, γ water-oil surface tension. When the field is sufficiently strong these ellipsoids arrange themselves to form water channels through the oil, causing short circuits. This theory agrees with exptl. data of Friese (*C. A.* 16, 2943); decreasing moisture content first causes a very slow, later on (for less than 0.1%) a rapid rise of the breakdown potential. Oil with 0.1% water, size of drops 2×10^{-3} cm., gives a calcd. value of 27 kv./cm., compared with the exptl. value 22 kv./cm. B. J. C. VAN DER HOEVEN

Asphalt. PRÉVOST HUBBARD. *Mineral Ind.* 33, 81-7(1924).—Discusses production, uses, tests and specifications, related hydrocarbons, etc. A. B.

Gas washing (WEISSENBERGER) (WEISSENBERGER, SCHUSTER) 13. Possible inorganic petroleum (LEWIS) 8. Poisoning by $PbEt_4$ (NORRIS, GETTLER) 11H. Apparatus for distillation of shale (U. S. pat. 1,554,587) 21. Filter for gasoline (Brit. pat. 230,991) 1. Distilling mineral oils (Brit. pat. 231,686) 13. Apparatus for separating water and impurities from hydrocarbons (U. S. pat. 1,555,231) 4.

Cracking hydrocarbon oils. E. C. HERTHEL and H. L. PELZER. Brit. 232,178, April 8, 1924. Pitchy substances are removed from oil undergoing cracking by passing the oil through a bed of fuller's earth or other absorbent clay, silica gel or equiv. material supported in the still. A portion of the pitch-laden oil is also withdrawn and replaced by fresh oil.

Cracking hydrocarbon oils. M. MELAMID. Brit. 231,190, March 22, 1924. Cracking of crude oil, tars or tar oils is carried out at temps. of 300-400° (by atomizing with H or gases contg. H in the presence of a catalyst which is liquid at the reaction temp.) so that only the lower-boiling constituents of the material treated are decomposed. Cf. *C. A.* 19, 892

Cracking hydrocarbon oils. E. W. ISOM. U. S. 1,553,168, Sept. 8. The oil is mech. circulated from and to a bulk supply tank through a heater, heated to a cracking temp. in the heater, and fresh oil is introduced into the circulating oil during the progress of distn. and is employed for cooling the circulating pump before introducing it into the distg. app.

Cracking hydrocarbon oils. GASOLINE PRODUCTS CO., INC. Brit. 232,283, Dec. 10, 1923. In gasoline production by cracking fuel oil, crude or topped oils, etc., a portion of the oil is cracked by passing it under pressure through a heated coil and into a reaction chamber. The cracked oil is blended on discharge from the reaction chamber into a vaporizing chamber with an oil which has been heated to a temp. sufficient to produce substantial distn. An app. is described.

Gasoline production by cracking of heavier hydrocarbons. A. D. SMITH. U. S. 1,550,115, Aug. 18. Residual liquid after cracking is filtered to remove the larger particles of free C, centrifuged to remove a portion of the colloidal C, and the purified liquid is then returned to the cracking zone. An app. is described.

Converting hydrocarbon oils. W. E. SHORE. Brit. 231,625, Feb. 13, 1924. A heavy oil to be converted into lighter products is atomized with H and the mixt. is subjected to compression considerably to raise its temp.

Still with internal electric resistance heater for cracking or converting hydrocarbon oils. O. P. AMEND. U. S. 1,553,300, Sept. 15.

Distilling hydrocarbon oils. W. B. LINDSAY and W. B. DAVIDSON. Brit. 232,347, Jan. 23, 1924. Crude or topped oil is distd. by spraying it into combustion gases such as those from a gas producer in which coke is burned with regulated air supply to avoid O and CO in the gas) mixed with cooler gases such as residual gases from the process or low pressure steam. Finely divided Fe may be blown into the vapors in, one of the condensers to effect a purification. An app. is described.

Pressure distillation and conversion of hydrocarbon oils. R. E. HUMPHREYS, F. M. ROGERS and M. G. PAULUS. U. S. 1,553,861, Sept. 15. In distg. "fuel oil" or similar oils to obtain hydrocarbons of lower b. p., the material is treated in a closed vessel in the vapor space of which about 4% or more of the vapors of the desired product are maintained (these having a b. p. of 120-205°) by exerting pressure on the vessel. Portions of the liquid petroleum material are converted into naphtha fractions b. at

120° or lower at the rate of 1.2% per hr. up to 17.7% per hr. (calcd. on the vol. of the charge) by maintaining the material at conversion temps. of about 400–430°. Gas from the conversion is removed from the still and passed through a condenser to recover hydrocarbons of low b. p.

Purifying hydrocarbons. AKT.-GES. FÜR CHEMIEWERTE. Brit. 231,900, April 5, 1924. Mineral oils and aromatic hydrocarbons such as C_6H_6 and xylene, after purification by acid, are neutralized without formation of emulsions by using lyes absorbed in solid carriers such as fuller's earth and kieselguhr. The oil is washed with H_2O after sepn.

Refining liquid hydrocarbons. A. E. DUNSTAN. U. S. 1,552,830, Sept. 8. Benzene, kerosene, shale oil or similar liquid hydrocarbon material is treated with an alk. hypochlorite soln. and then with caustic alkali soln. Another batch of hydrocarbon material, before treatment with the hypochlorite, is washed with the residual caustic alkali soln.

Purifying liquid hydrocarbon oils. F. B. THOLE and S. T. CARD. Brit. 231,944, Jan. 11, 1924. In desulfurizing liquid hydrocarbons with alk. solns. of hypochlorites, the free alkali content is reduced during or immediately prior to the treatment, preferably by passing CO_2 into an agitated mixt. of the oil and alk. hypochlorite to react with all the NaOH present. $FeCl_3$ and the sulfates of Fe, Zn, Mn and Mg also may be used to react with the free alkali.

Apparatus for dephlegmation and rectification of hydrocarbon vapors. D. PYZEL. Brit. 231,334, April 22, 1924.

Oil from shale. G. A. BRONDER. U. S. 1,552,539, Sept. 8. Shale is heated to effect distn. while carried by a conveyer.

Filtering material from shale residue. D. T. DAV. U. S. 1,555,639, Sept. 29. Porous spent shale material of a siliceous nature such as that left as a residue after oil distn. from shale is heated with a strong NaOH soln., forming Na silicate in its pores, then treated with H_2SO_4 to form free silicic acid in the pores, washed with H_2O to remove Na_2SO_4 and heated to low redness. U. S. 1,555,640 specifies heating a mixt. of shale and alkali and grinding the product.

Rotating retorts arranged in series, adapted for distilling oil from shale. F. S. BACON. U. S. 1,556,194, Oct. 6.

Converting oils. BENZONAFTENE. Brit. 231,157, March 24, 1924. Heavy oils such as fuel oils and fatty substances of animal, vegetable or mineral nature are treated to yield "liquids analogous to petroleum or naphtha" and a gas suitable for lighting or heating purposes. The materials are heated to 450–600° with Ce oxide and reduced Cu and are then subjected to the action of Th oxide and reduced Ni at the same temp. Hydrocarbon vapors are sep'd in a condenser which is maintained at a temp. of about 30° and the remaining vapors are subjected to the action of Fe oxide and reduced Ni at 200° and are cooled to 15° to sep. additional hydrocarbon liquid. The still uncondensed vapors are treated with Fe oxide and reduced Fe at 250–300° and cooled to 10° to sep. more liquid. Brit. 231,459 specifies an app. for carrying out this process. Brit. 231,460 specifies withdrawal of the gases produced from processes of this character, compressing them to 20 atm, and passing them through a liquid separator and cooler to effect liquefaction. The liquid thus obtained is subjected to fractionation to obtain rhigolene, petr. ether, gasoline and ligroine. The uncondensed gases pass through a washer contg. H_2SO_4 heated to 150°, or Br, to absorb C_2H_4 and thence to a scrubber and holder. They may be used to heat the still.

Cracked hydrocarbon products. BENZONAFTENE. Brit. 231,461, March 28, 1924. Liquid hydrocarbons prep'd. as described in Brit. 231,157 and 231,459 (cf. above) are distd. in a furnace-heated still and different fractions of the distillate are treated with conc'd H_2SO_4 and NaOH and air, further distd. and the vapors are passed through purifiers contg. Ca and Mg oxides and filters contg. animal black. Part of the still residues is mixed with vegetable pitch, oil and rubber and used for manuf. of elec. insulation and part may be burned to produce lamplack. Another portion is mixed with heavy oil, MnO_2 and colophony to produce a siccative oil similar in properties to linseed oil.

Dephlegmating dome for oil-converting apparatus. J. H. ADAMS. U. S. 1,549,894, Aug. 18.

Heating tubular stills for cracking oils, etc. J. E. BELL. Brit. 231,840, April 1, 1924. Furnace gases used for heating oil tubes are mixed with preheated gas or air of somewhat lower temp. before being brought into contact with the oil tubes.

Asphalt fluxing oil. W. M. BURTON. U. S. 1,553,847, Sept. 15. Fuel oil or a similar petroleum oil is distd. under pressure until a substantial proportion of its con-

stituent hydrocarbons has been converted into hydrocarbons of lower b. p. and distn. off. The tarry residue is then subjected to distn. in the presence of open steam until its Engler viscosity at 100° is approx. 6.

Oil refining. J. MCK. BALLOU. U. S. 1,553,973, Sept. 15. Heated crude petroleum oil is injected into a sepg. compartment and maintained under pressure by a special arrangement of the app., to prevent foaming.

Aluminium chloride. F. W. HALL. U. S. 1,549,766, Aug. 18. Acid sludge from oil refining is heated to render it liquid, mixed with powd. Al ore such as bauxite so that the latter is in suspension, and the mixt. is coked and chlorinated to produce $AlCl_3$.

Breaking petroleum emulsions. W. S. BARNICKEL. U. S. 1,555,818, Oct. 6. Petroleum emulsions such as those contg. brines are broken by the use of Cl, Br or nitro derivs. of resin or other deriv. of a resin in which the substitution or addn. occurs in the hydrocarbon radical. Cf. C. A. 19, 1625.

Apparatus for determining the burning and flashing points of petroleum oils. C. PETTELE. U. S. 1,554,993, Sept. 29. Oil to be tested is placed in a groove within a horizontal cylinder of uniform cross-section, one end of the cylinder is heated and the oil adjacent this heated end is ignited. The temps. of the oil at points along the groove where it is burning and flashing are noted.

Apparatus for cracking and distillation of petroleum oils. L. C. HUFF. U. S. 1,555,976, Oct. 6.

Apparatus adapted for distillation of petroleum oils. M. J. TRUMBLE. U. S. 1,555,531, Sept. 29.

Apparatus for continuous distillation of crude petroleum or similar oils. J. F. BLAISE. U. S. 1,552,980, Sept. 8.

Petroleum still of the column type. S. T. SMITH. U. S. 1,556,132, Oct. 6. The still is adapted for distg. gasoline (from natural gas) after its absorption in oil.

High-pressure still for distillation of petroleum oils. W. F. SCHANZLIN. U. S. 1,555,761, Sept. 29.

Petroleum oil still. F. M. HESS. U. S. 1,552,698, Sept. 8.

Preheater for petroleum stills. H. A. HILLS. U. S. 1,552,433, Sept. 8.

Apparatus for separating oil and gas in wells. J. COULTER. U. S. 1,554,842, Sept. 22.

Gas trap for treating oil from wells. M. J. TRUMBLE. U. S. 1,554,471, Sept. 22.

Apparatus and procedures for making electric conductivity tests in oil wells, etc. F. W. HUBER. U. S. 1,555,800-1-2-3, Sept. 29.

Apparatus for separating water from gasoline, etc. J. ZWICKY. Brit. 232,287, Dec. 17, 1923.

Emulsions for binding fuels and for other purposes. J. C. MORRELL. U. S. 1,556,005, Oct. 6. The fluidity of emulsions is regulated by blending different emulsions of asphalts and oils or other material of relatively different fluidities.

Purifying oils. P. T. SHARPLES and L. D. JONES. Brit. 231,877, April 2, 1924. Used lubricating oils from internal-combustion engines, etc., are purified by centrifuging or by treating the oil in finely dispersed condition with air or gas or "oxidizing or chemical agents."

Purifying oil. L. H. CLARK. U. S. 1,553,141, Sept. 8. Impure oils such as used transformer or lubricating oils contg. finely divided C are treated with NaOH soln. or other aq. alk. reagent sufficiently dil. that H_2O -sol. impurities and reaction products will be in soln. in the aq. phase formed and the mixt. is subjected to centrifugal sepn.

Lubricants. M. J. HEITMANN. Brit. 232,259, April 10, 1924. Lubricants for axles of trucks and other machinery are formed of solid mineral oil contg. up to 50% or more of H_2O which may be emulsified with the oil by use of polymerized oils such as "voltol," wool fat, wool fat alcs., and montan wax. The emulsion may be prepd. by atomization or by use of steam.

Lubricant. A. E. BECKER and L. D. HISLOP. U. S. 1,552,669, Sept. 8. *A lubricant comprises Na naphthenate, petrolatum, still wax and H_2O , in various proportions.

Oil mixture containing camphor. J. A. YOUNG. U. S. 1,555,899, Oct. 6. A compn. adapted for lubricating leaf springs, etc., is formed of camphor 1 dissolved in a mixt. of lubricating oil 8 and crude petroleum 23 parts.

Apparatus for distilling diluents from crank case oil by use of heated air. E. J. HALL and C. A. WINSLOW. U. S. 1,555,664, Sept. 29.

Distilling bituminous schist, asphalt or lignite. SOC. LYONNAISE DES SCHISTES BITUMINEUX. Brit. 231,453, March 26, 1924. Distn. is effected by internal heating in a vertical cylindrical retort to which gas, steam and air are admitted to maintain a reducing atm. in the retort.

23—CELLULOSE AND PAPER

CARLETON E. CURRAN^{*}.

Dispersoidological investigations. IV. Dispergation and aggregation in general and particularly in their application to cellulose. P. P. VON VEIMARN. *Reports Imp. Ind. Research Inst., Osaka, Japan* 5, No. 18, 7-185(1925); cf. *C. A.* 18, 926.—V.'s work, which is actually a monograph on dispergation and aggregation, is divided into 4 parts. (1) a general part that is largely theoretical (pp. 7-107); (2) an exptl. part; (3) a brief program of further investigations on cellulose (pp. 171-6); (4) and an appendix (pp. 179-85) giving a translation of D. R. P. 275,882(1921), outlining a method for the conversion of celluloses of all kinds into plastic or gelatinous masses or into colloidal solns. Part (1) gives in detail V.'s views on dispergation. A dispersoidal ppt. of a solid substance is a ppt. made up of individual crystals of a size smaller than 200μ . These individual crystals may be in the form of unordered or orientated aggregates, such as threads, flakes, fibers, etc., that may be microscopic or macroscopic in size. V. discusses the chem. compn. and purification of ppts., and points out that "one cannot be cautious enough in accepting the various deductions made on the ground of the classical methods of pure chemistry, concerning the chem. formula of cellulose as a chem. individual." Until cellulose crystals can be grown to microscopic size at least, no purification will be sufficient to permit adequate investigations on the chem. constitution of cellulose. Tentatively, however, V. accepts Herzog's X-ray data indicating that celluloses of various origins contain largely one and the same chem. individual. Fibers of various kinds of cellulose are regarded as aggregate particles, consisting of minute ultramicro-crystals, probably rhombic, which are present in an axial arrangement more or less parallel to each other. The superficial layers of these crystals are probably contaminated with extraneous material, as are the ultramicro-pores of the fibers. The dispersoidological properties of the various cellulose fibers depend upon: the dimensions of individual ultramicro-cryst. particles, the firmness of the bonds holding these particles together, the degree of orientation of these particles, and the nature and concn. of the impurities present in the fiber. Part (1) also takes up the mechanism of the general dispergation process as applied to (a) molecularly or atomically non-homogeneous crystals; (b) crystals in which the vectorial structure is deranged; and (c) aggregates of crystals. The mech. dispergation of different types of cellulose (with illustrations of various types of dispergators = colloid mills) are discussed in detail. To obtain the best results with dispersoid mills, cellulose should be allowed to swell in water or in salt solns., and should then be disintegrated at -80° , or below. Very slight dispergation of cellulose, usually less than 0.01%, but at times 0.1%, may be caused by mechanically shaking S. and S. filter-mass No. 292 with 2 l. of distd. H_2O for 1 hr. V. has shown by ultraphotomicrographs that solns. show the Brownian movement. Preliminary expts. also show that cellulose may be partially dispergated by aq. solns. contg. 0.08 mols. of Na citrate per l. V. reiterates his former statement that all readily sol. salts will serve to dispergate cellulose provided the proper conditions of temp. and pressure are maintained. V.'s concepts of adsorption and solvation are also given in some detail. Dispersoidal "parasitism" may be manifested in cellulose solns., when products of cellulose decompn., which are more readily dispersed than the unmodified cellulose, act as dispergators for the cellulose particles. The fact that these initial decompn. products are also dispersoids was shown by ultramicroscopic examn. of their solns. V. discusses general aggregation processes, and then takes up the case of dispersoidal cellulose solns. Two extreme types of cellulose solns. exist: (a) solns. yielding elastic continuous jellies, (b) solns. failing to produce an aggregatory effect or gradually yielding ppts. consisting of aggregate particles. These types are connected by intermediate transition forms. Type (a) is discussed very fully with special reference to process of formation, structure and properties. Cellulose jellies that have been washed to remove salts, shrink rather rapidly, become denser, and acquire increased tensile strength. When dried completely the jelly becomes brittle, but still preserves its tensile strength. Transition from cellulose jellies to plastics (ointment-like masses) is dependent on the concn. of products of cellulose hydrolysis in the gels. Beyond a certain concn. of such products, the properties of jellies change from elastic systems into the region of plastic masses. The exptl. part (2) is in part a résumé of older work, including some of the fragmentary expts. carried out in Russia in 1911-13. Priority is again claimed for the work on thiocyanates usually accredited to Williams (*C. A.* 16, 340). Earlier work on the dispergating action of NaCl and BaCl₂ was repeated more carefully and confirmed. In each set of expts. a large excess of the salt was added to 200 cc. H_2O in which were

suspended 4 g. S. and S. No. 292 cellulose tablets. The sealed flasks contg. the cellulose-salt mixts. were gradually heated between 105° and 182°. In the case of NaCl, intensive dispersion was noted at 180°. With BaCl₂ pronounced dispersion began at a somewhat lower temp. Partial hydrolysis set in, in either case, and the hydrolysis products were amicroscopic and formed very stable sols. Ultramicroscopic examn. of sols. and ppts. indicate that some of the cellulose particles are certainly of dispersoidal size, and the ppt. may in part be dispergated with hot or cold water, thus forming cellulose sols having low salt concns. A large part of the cellulose dissolved in the concd. salt sols. is pptd. in gelatinous form, sepg. on the crystd. salts. V. has also shown that 5-6 g. cellulose may be readily dispergated at 160° by 100 cc. of satd. aq. LiCl, and that the soln. deposits snow-white flakes of cellulose. If the concn. of cellulose is raised to 10-12 g. per 100 cc. of LiCl soln., a viscous deep brown soln. is obtained which sets to a jelly pierced with LiCl crystals. (Exptl. conditions are given in great detail.) 100 g. of Ca(CNS)₂ soln. satd. at 50° readily dispergated 2 g. cellulose at 105°, forming a pale transparent jelly on cooling. If 8 g. of cellulose are used, and the heating is continued to 125-35°, a very dark but firm and elastic jelly is obtained after cooling. Heating above this point leads to soap-like ointments. Dwindling of elasticity of the jelly is so gradual that it becomes impossible to draw a line between a jelly and a semi-solid ointment. Numerous ultraphotomicrographs of the various sols, ppts., fibers, jellies and ointments are included. Dispersoidal sols. of cellulose contg. degradation products may be formed by treating cellulose ppts. deposited from concd. salt sols., and washed nearly free from salts, with boiling H₂O. The aq. layer above the cellulose may be decanted off after standing 42-66 hrs., and this operation repeated with each cellulose residue until a number of successive "disperse systems" have been obtained. A well defined dispersion max. occurs in such a series. At this max., the cellulose soln. shows the most pronounced bluish white opalescence of any prepn. of the series, and the cellulose and salt concns. are exceedingly low. A cellulose ppt. obtained from a concd. LiCl soln. was dispergated by a series of treatments with boiling H₂O, and 14 successive sols. were prepd. Of these the 9th prepn. (cellulose concn. = 0.08 g. per l.; LiCl, 0.07 millimol. per l.) showed the dispersion max., and was also shown to be the most stable soln. of the series. When concd. sols. that have been heated under pressure with cellulose are poured into H₂O, to yield a medium salt concn., and allowed to stand for several months, the supernatant liquid is yellow and exhibits a bluish white opalescence, which may or may not be susceptible of differentiation into sep. particles. These sols. also have a marked reducing action in dil. sols. of Ag and Au salts, and yield very stable and highly disperse sols. of dispersoidal Ag and Au. V. gives conditions for the prepn. of such sols. in daylight and in partial darkness, and describes their properties in minute detail. V. points out that at room temp. and in complete darkness, the yellow sols. may fail to exert any reducing action on Ag halides, but might render Ag salts very sensitive to light. (This has not been proved by expt.) The porosity and absorption capacity of a cellulose gel prepd. from Ca(CNS)₂-cellulose soln. showed that a white elastic ball of cellulose jelly could be washed practically free from salt by H₂O, followed by treatment with alc. The cellulose gel was finally treated with Et₂O and dried over H₂SO₄. When 7 g. of cellulose were used in the prepn. of a gel, the dried gel weighed 7.3 g. and had a diameter of 5 cm., and resembled dried gluten in consistency. It absorbed 700% of its dry wt. of H₂O, without recovering its original wet vol. (approx. 150 cc.), and while still manifesting a wrinkled surface. The dried cellulose ball showed a cabbage-head structure, and was apparently built up of cellulose plates, placed one over the other. V. **Quantitative study on cellulose dispersion in aqueous solutions of Ca(CNS)₂ saturated at room temperature and at 50°.** P. P. VON VEIMARN AND S. OTSUKA. *Ibid* 189-200.—Ca(CNS)₂ sols. were prepd. by satg. at 20° (room temp.) and at 50°. Cellulose (S. and S. tablets) in carefully weighed amts. was allowed to remain in contact with these sols. and the mixts. were then heated at a definite temp. until complete dispergation (as detd. by the ultramicroscope) had taken place. Time-temp. dispergation curves were constructed for sols. contg., resp., 2, 4, 5, 6 and 8 g. of pure cellulose in 100 cc. of soln., and also for sols. contg. 2 and 4 g., resp. of sulfite pulp. The latter failed to give transparent sols. and the rate of dispergation was much slower than that of pure cellulose. The rate of dispergation increases with increasing temp., and decreases with increasing amts. of cellulose. A 2% soln. of cellulose in Ca(CNS)₂ satd. at 20°, may be obtained at 90° in about 7 hrs. and at 110° in less than 2 hrs. The rate of dispergation of the cellulose depends also on the previous treatment of the sample; e. g., if a sample was previously shaken during 24 hrs., it could be completely dispergated at 80°. The following data give, resp., the wt. of cellulose taken, and the time and temp. of complete dispergation, using 100 cc. of

Ca(CNS)₂ solns. satd. at 20°: 4 g. in 4.5 hrs. at 100°, 3 hrs. at 110°, 3 hrs. at 120°; 5 g. in 6 hrs. at 100°, 4 hrs. at 110°, 4 hrs. at 120°; 6 g. in 8 hrs. at 100°, 5.5 hrs. at 110°, 5 hrs. at 120°; 8 g. in 7 hrs. at 110°, 6 hrs. at 120°. The following are similar data obtained with pure cellulose using 100 cc. of Ca(CNS)₂ satd. at 50°: 4 g. in 4 hrs. at 100°, 1.5 hrs. at 110°, 1 hr. at 120°; 10 g. in 4 hrs. at 120°, 1.5 hrs. at 130°. Each soln. was carefully explored with the ultramicroscope, and numerous photomicrographs and ultraphotomicrographs are given. LOUIS E. WISE

Evolution of celluloid and of nitrocellulose collodions. A. BRÉGUET. *Rev. gén. colloïdes* 3, 200-6, 230-5(1925).—The changes taking place in celluloid and in nitrocellulose (A) collodions with time and after treatment with heat and with ultra-violet light, were studied by fractional pptn. of A by Duclaux and Wollmann's method (C. A. 14, 3154), using C₆H₆ instead of H₂O to prevent pptn. of the camphor, and detn. of the wt., viscosity and N content of the various fractions. The results are interpreted in the light of Duclaux' theory of the constitution of reversible gels (C. A. 17, 1567), as follows: in a collodion the most complex A mols. have the greatest tendency to polymerize and swell; and in an A sol the solid phase (cellular network) is formed of the largest granules, the cells of which are filled with a dispersion of the finer granules in the solvent. The granules of collodion are in equil. with the solvent, and in time the cohesion forces of the mols. in the granules gradually diminish, and the granules are progressively depolymerized with resultant decrease in swelling. This is manifested by decrease in viscosity. This aging does not proceed indefinitely, but tends to a limit which depends on the concn., temp. and also on the nature of the A. Aging is accelerated by heat, light and mechanical treatments. The changes taking place in collodion with time are thus due to its changing from an emulsoid to a suspensoid. The above conclusions are applicable in their entirety to celluloid and particularly to cinematographic films, which consist merely of a highly concd. solid dispersion of A in camphor. A. PAPINEAU-COUTURE

Bleaching chemical wood pulp. L. DEMARS. *Mon. papeterie belge* 5, 475-85, 541-58(1925).—General and fairly detailed discussion of the purpose, mechanism and methods of carrying out pulp bleaching operations. A. PAPINEAU-COUTURE

Starches as pasting materials. H. M. GRASELT. *Paper Ind.* 7, 900-1(1925).—Brief description of the prepn. of starch pastes for use on paper pasting machines. A. PAPINEAU-COUTURE

Recent research of the U. S. Bureau of Standards. B. W. SCRIBNER. *Paper Trade J.* 81, No. 13, 51-6(1925).—A brief description of investigations on paper testing, manuf. and specifications recently completed or in progress at the present time. A. PAPINEAU-COUTURE

Hydrogen-ion concentration in the paper mill. M. B. SHAW. *Paper Trade J.* 81, No. 10, 59-62(1925).—An explanation of the meaning of p_H and of its colorimetric detn., with an account of tests carried out at the Bur. of Standards paper mill, showing its importance in *paper sizing*. Max. pptn. of alum occurs at p_H of 5.0-5.5, depending on the parts per million of alum used. By regulating the p_H of the stock in the beater after pptg. the size, the alum consumption in the mill has been reduced by 33%. The use of H₂SO₄ to produce the proper p_H does not give satisfactory sizing. A certain amount of colloidal Al hydroxide, supplied by alum, is required for effective sizing, but the amount is min. at the optimum p_H value. The quantity in excess of that required to produce this value apparently has no favorable effect on the sizing quality of the paper. A. PAPINEAU-COUTURE

Indicators for the pulp industries. F. ÖMAN. *Pulp Paper Mag. Can.* 23, 981-4, 1011-2, 1016, 1035-6, 1059-60(1925).—See C. A. 19, 2743. A. P.-C.

Paper making woods of other Dominions. ANON. *Pulp Paper Mag. Can.* 23, 1101-3(1925).—A discussion of the suitability for pulping of the most important woods of Australia, New Zealand and India. A. PAPINEAU-COUTURE

Esparto as a paper making material. M. B. SHAW, G. W. BICKING AND R. R. RUMSEY. *Paper Trade J.* 81, No. 12, 55-6(1925).—Lab. and semi-com. pulping tests were carried out on esparto "semi-pulp" now available on the American market. Best results were obtained with 5% NaOH (on the wt. of grass), and the fiber obtained was appreciably stronger than soda pulp and approached sulfite in strength. In order to obtain a clean sheet, free from specks and shives, it was necessary to clean the pulp mechanically before cooking. The lab. cooks (without dusting) gave 73-8% yields, and the semi-com. cooks (with dusting) gave 57-63% yields. A. P.-C.

Bamboo and grasses for paper pulp. W. RAITT. *World's Paper Trade Rev.* 84, 562-8, 618-20(1925).—A detailed description of R.'s "fractional" boiling process for the pulping of bamboo and grasses (C. A. 8, 247; 11, 1546; 16, 1012) with a discussion

of its merits. With *sabai grass* the fractional process reduces NaOH consumption from 15 to 11.5%, cooking temp. from 145° (45 lbs. pressure) to 136° (32 lbs. pressure), time from 4 hrs. to 3.5 hrs., bleach consumption (on the wt. of grass) from 6 to 1.75%, spent liquor from 1400 gal. at 5.5° Tw. to 900 gal. at 11° Tw., and gives 2% higher yield of bleached pulp. Similarly, with bamboo, fractional boiling reduces NaOH consumption from 21 to 15%, cooking temp. from 162° (80 lbs.) to 140° (38 lbs.), bleach consumption from 10 to 5%, and spent liquor from 1600 gal. at 6° Tw. to 1000 gal. at 10.5° Tw., and increases the yield of bleached pulp by 3%. Practical hints are given on the prepn. of bamboo for pulping, more particularly as regards splitting and crushing, and "seasoning" under water to remove a considerable proportion of its starchy constituents which facilitate molding and attacks by insects.

A. PAPINEAU-COUTURE

New method of cooking straw for strawboard. J. D. RUE AND W. H. MONSSON. *Paper Trade J.* **81**, No. 15, 52-3(1925).—Digestion of straw with a soln. of Na_2CO_3 and Na_2SO_3 gives a higher yield of a product which possesses less odor, has superior phys. properties, contains less ash and more cellulose and is more resistant to the action of 1% NaOH than the product obtained by the ordinary CaO process. The most favorable proportions of chemicals are 7.5 lbs. Na_2CO_3 and 1.5 lbs. Na_2SO_3 per 100 lbs. of straw. Recovery of the Na_2O is not economically necessary but can be applied. The cost of the new product may be up to \$3.13 per ton greater than that of straw pulp produced by the CaO process; but the difference in most cases would be much less or would be compensated for by higher yields and improved quality. A. P.-C.

Proposal for reducing the contamination of streams by strawboard mills. J. D. RUE AND F. G. RAWLING. *Paper Trade J.* **81**, No. 15, 48-9(1925); cf. preceding abstract.—Recovery of the Na_2O in the Na_2CO_3 - Na_2SO_3 process will eliminate most of the stream pollution. As only about 25% of the SiO_2 in the straw is dissolved out by this process, it would not cause trouble in incineration, nor in the settling of the sludge as the black ash is not causticized. From a discussion of the cost of the recovery process, R. and R. conclude that the additional cost of the product will not be prohibitive, specially in view of the demonstrated superiority of the strawboard produced.

A. PAPINEAU-COUTURE

Evaporating black liquor. R. W. MACGREGOR. *Paper Trade J.* **81**, No. 14, 57-8(1925); *Paper Mill* **49**, No. 40, 10, 46(1925).—Brief discussion of the advantages of multiple effect vacuum evaporators over disc evaporators for the concn. of black liquor.

A. PAPINEAU-COUTURE

Colored back water and two sidedness in paper mills. J. R. ROBERTS. *Paper Trade J.* **81**, No. 14, 55-6(1925); *Paper Mill* **49**, No. 40, 12, 42(1925).—Both the color of the back water and the evenness of color of the 2 sides of the sheet depend to a large extent on the retention of the dye or pigment by the stock, and the troubles are largely or wholly overcome by sufficiently increasing the affinity of the dye for the fibers. The following will help reduce the trouble: select direct dyes if possible, use salt and heat in the beaters, with double deck driers shut off the steam from the first one or two driers which the bottom (or wire) side of the sheet strikes. Practically every case must be studied separately owing to differences in the conditions prevailing in different mills.

A. PAPINEAU-COUTURE

Testing method for degree of sizing paper. F. T. CARSON. *Paper Trade J.* **81**, No. 15, 47(1925); cf. C. A. **19**, 175.—A comparative study was made of the ink flotation, electrolytic or conductivity (2 types), Stockigt, curl and Bureau of Standards new indicator methods for detg. degree of sizing. Exptl. data obtained on 63 samples of paper appear to justify the following conclusions: (1) The most probable relative degrees of internal sizing of the various samples tested are best represented by the data of the Bureau of Standards indicator method. (2) The agreement between the indicator method and the curl method is in general satisfactory. (3) The Stockigt method is fairly dependable, but there is attached an element of uncertainty which at times may involve gross error. (4) Neither the electrolytic method nor the ink flotation method corroborates any other method, nor can these methods be depended upon to give consistent or reasonable comparative data even on the same kind of paper. A. P.-C.

Cellulose xanthates. R. WOLFFENSTEIN AND E. OESER. *Kunstseide* **1**, 2-5, 27-31, 74-8(1925).—By treating acetone-sol. cellulose acetates with NaOH and then CS₂ according to the technical methods of viscose manuf., a product named *cellulose dithionate* may be obtained which differs from the ordinary form in that the ppt. obtained by diln. with EtOH is dark brown and gummy, and further contains about 45% cellulose. It is believed that under the conditions 5 OH groups of the cellulose mol. are made reactive. The compd. is less stable than the common xanthate, the de-

compn. of metallic derivs. being particularly rapid. The secondary increase in viscosity of viscose solutions on ripening is apparently caused by the sepn. of cellulose. E. R. CLARK

Utilizing waste gases from cookers in the cellulose industry. H. KOCH. U. S. 1,554,581, Sept. 22. Waste gases such as are evolved from cookers in which cellulose material is digested with sulfite soln. are subjected to elec. pptn. at a temp. sufficiently high to prevent condensation of H_2O , in order to sep. org. substances such as aromatic compds.

Reinforced cellulosic sheets. E. C. NOONAN. U. S. 1,550,041, Aug. 18. A roll of wire netting is submerged in a body of paper pulp to fill its meshes, withdrawn and passed over a rotating heated roll.

Cellulose derivatives, etc. L. LILIENFELD. Brit. 231,807, April 4, 1924. Cellulose derivs. sol. in aq. alkalis but insol. in H_2O and in the usual org. solvents are obtained by acting on cellulose or an alkali-insol. cellulose conversion product with a halohydrin such as α -monochlorohydrin or ethylene chlorohydrin in the presence of an alkali soln. The products are inert, resistant to alkalis, and are suitable for the manuf. of threads, films, etc.

Cellulose oxy-alkyl and hydroxy-alkyl ethers and compositions made therefrom. L. LILIENFELD. Brit. 231,808, April 4, 1924. Oxy-alkyl and hydroxy-alkyl cellulose ethers such as are produced by the process of Brit. 231,807 (cf. above) are used in the manuf. of coatings, sizes, artificial leather, cements, thickening agents for pigments in textile printing, plastic compns., films and artificial threads. The ethers may be used in alkali soln. and may be mixed with other colloids and softening agents such as hydrated cellulose or hydrocellulose sol. in alkalis, viscose, albuminous substances, proteins, gelatin, amyloid, starch, dextrin, gums, pectins, tragacanth, resins and resinous condensation products sol. in alkalis, shellac, glycerol, diglycerol, polyglycerol, glycols, sugars, sirups, soaps, fats and NH_4 or alkali metal derivs. of fatty sulfonic acids such as Turkey-red oil.

Cellulose ethers, etc. L. LILIENFELD. Brit. 231,809, April 4, 1924. Cellulose derivs. insol. in H_2O but sol. in aq. alkalis are prepd. by carrying out the treatment of cellulose or a cellulose conversion product insol. in alkali, with a monohalogen fatty acid or a salt or ester of such an acid, and alkali, without the use of alc. or with the use of not more than 20% as much alc. as H_2O . Details of proportions and strengths of reagents are given and among the acids which may be used are: monochloroacetic acid, α -bromopropionic acid, bromosuccinic acid, α -bromoisobutyric acid. The products may be pptd. from the reaction mixt. by use of an acid, acid salt or alc. and may be used for the manuf. of transparent threads or films or other products. Brit. 231,810 specifies a similar process in which an alc. is used and in which the mol. proportion of halogen fatty acid to caustic alkali used is not more than 0.5:1, e. g., 0.3:1. Brit. 231,811 specifies the use of cellulose derivs. such as are obtained according to Brit. 231,809 in the manuf. of a large variety of compns. and mixts. for threads, films, coatings, adhesives, artificial leather, etc.

Cellulose derivatives. L. LILIENFELD. Brit. 231,800, April 4, 1924. A cellulose xanthic acid or xanthate is treated with a halogen fatty acid or with one of the salts, esters or derivs. of such an acid, e. g., $ClCH_2CO_2H$, $CH_3CHBrCO_2H$ or $C_2H_5CHBrCO_2H$. The products are either sol. in H_2O , sol. in aq. solns. of NH_3 and of aliphatic and aromatic bases or in aq. solns. of caustic alkalis and are suitable for making threads and films. Brit. 231,801 specifies treating these products (either in a unitary operation with their formation or subsequently as a sep. step) with compds. such as $PhNH_2$, o - $CH_3C_6H_4NH_2$, $EtNH_2$, Et_2NH , $MeNH_2$ or $PhCH_2CH_2NH_2$. The products are insol. in H_2O , alc. or ether but are sol. in dil. caustic alkali and in aq. NH_3 solns. and in org. solvents such as pyridine, aniline and chlorohydrins, "especially in aq. soln." Brit. 231,802 specifies the use of NH_3 instead of the amines used according to Brit. 231,801. The products obtained with NH_3 are insol. in H_2O but sol. in aq. alkalis and are suitable for making strong threads or films.

Products from cellulose derivatives of xanthic and fatty acids. L. LILIENFELD. Brit. 231,805, April 4, 1924. Compds. as produced according to Brit. 231,800 (cf. above) are used for the manuf. of finish coatings, sizes, artificial leather, cements, thickening agents for pigments in textile printing, plastic compns., films and threads. The cellulose deriv. may be used as an aq. soln. or with volatile basic substances such as NH_3 , or members of the guanidine, pyridine or quinoline groups. Various fillers, coloring materials and other auxiliary ingredients are specified for various purposes.

Molded and other articles from substituted cellulose thiourethans. I. LILIENFELD. Brit. 231,806, April 4, 1924. Substituted cellulose thiourethans such as are obtained by the process of Brit. 231,801 (cf. above) are used in the manuf. of substitutes for celluloid, ivory, glass, horn, ebonite, tortoise-shell, wood, paints or lacquers, resins and resin substitutes, films, artificial silk, adhesives, printing rollers and hectographic masses, artificial leather and finishes for cloth and paper. Numerous examples are given of mixts. with a large variety of auxiliary and modifying ingredients for making mixts. for the specified and other purposes.

Cellulosic esters. P. BERTHON. U. S. 1,553,924, Sept. 15. Hydrocellulose is mixed with palmityl chloride (dild. in CHCl_3) or other acid chloride of the acylic org. acids contg. more than 5 C atoms, an org. base such as pyridine or quinoline is added, the materials are heated, the cellulose ester formed is pptd., *e. g.*, by adding alc., and is washed and dried.

Cellulose esters and ethers. SOC. CHIMIQUE DES USINES DU RHONE. Brit. 231,837, April 2, 1924. A rotary drum without fixed internal agitating devices is used for making cellulose esters and ethers and balls, rolls or the like may be loosely placed in the drum to facilitate mixing.

Cellulose ether composition. S. J. CARROLL. U. S. 1,552,792, Sept. 8. A cellulose ether, *e. g.*, the Et ether (insol. in H_2O), is homogeneously mixed, in unpptd. form, with resorcinol diacetate to form a compn. adapted for making films.

Cellulose ether compositions for films, etc. S. J. CARROLL. U. S. 1,552,793, Sept. 8. Resorcinol is used with cellulose ethers such as the H_2O -insol. Et ether, the ingredients being mixed in unpptd. form. U. S. 1,552,794 specifies Et acetanilide instead of resorcinol. U. S. 1,552,795 (H. T. CLARKE) specifies pentaerythritol tetraacetate. U. S. 1,552,796 (J. M. DONOHUE) specifies Et lactate. U. S. 1,552,797 specifies C_6H_6 and acetone. U. S. 1,552,798 specifies benzyl chloride or other "aliphatic halide deriv. of toluene". U. S. 1,552,799 specifies a bromo-nucleo benzenoid substitution product such as $\text{C}_6\text{H}_5\text{Br}$, $\text{C}_6\text{H}_4\text{Br}_2$ or monobromotoluene. U. S. 1,552,800 specifies acetylacetone. U. S. 1,552,801 specifies hexyl acetate. U. S. 1,552,802 specifies cannone. U. S. 1,552,803 specifies hydroquinone diacetate or other acetic ester of a polyhydroxybenzene. U. S. 1,552,804 specifies Pr, Bu or Am butyrate. U. S. 1,552,805 specifies a carbonic ester of a lower monohydroxy aliphatic alc. such as Et carbonate. U. S. 1,552,806 specifies Me formate.

Crinkling and "delustering" cellulose ester fibers. H. DREYFUS, J. F. BRIGGS and H. R. S. CLOTWORTHY. U. S. 1,554,801, Sept. 22. Threads or fibers of cellulose acetate or similar material are treated with a reagent such as hot H_2O or NH_4CNS soln. to give them the effect of wool, hair, etc.

Solvents for cellulose esters, etc. M. OW-ESCHINGEN and E. PFIFFNER. Brit. 231,161, March 24, 1924. Oily liquid residues obtained in the distn. of crude "wood alk." are used as solvents for nitrocellulose, acetylcellulose, cellulose ethyl ether, etc., after a redistn. or fractionation. Nonsolvent fractions may be mixed with MeOH, EtOH or $\text{C}_6\text{H}_5\text{Cl}$ to form solvent mixts.

Nitrocellulose composition. W. M. JOHNSON. U. S. 1,554,505, Sept. 22. A plastic non-inflammable nitrocellulose compn. is formed of a celluloid mass mixed with a lesser proportion of a mixt. contg. CaCl_2 2, NaOAc 1, alum 1, Na borate 1 part and a camphorated alc. soln.

Compositions of nitrocellulose or other cellulose esters. E. E. REID. U. S. 1,554,033, Sept. 15. A neutral Bu phthalate, *e. g.*, di-(normal) Bu phthalate, is used as "modifier" or softener with nitrocellulose or other cellulose esters in forming compns. adapted for making films, artificial leather, lacquers, etc.

Reducing the viscosity of nitrocellulose solutions. G. C. BAGON. U. S. 1,553,494, Sept. 15. Nitrocellulose is heated in the presence of a liquid such as mixed EtOH and C_6H_6 which possesses a low solvent power, to render the nitrocellulose sol. in the liquid and form a soln. adapted for use as a *varnish or lacquer*. U. S. 1,553,495 specifies embedding nitrocellulose in a body of sand or other substantially dry protecting and heat-transmitting medium and then subjecting the embedded material to heating, at a temp. of about 60–100° or higher, to reduce its viscosity when dissolved in solvents such as alc and C_6H_6 .

Dehydrating nitrocellulose. J. H. HASTR. U. S. 1,552,807, Sept. 8. Washed nitrocellulose is treated with alc. to remove H_2O and then treated with monochloronaphthalene, which serves to lessen the fire risk in handling the material.

Paper pulp manufacture. V. BERNOT and P. R. FOURNIER. U. S. 1,553,976, Sept. 15. Mech. features.

Apparatus for bleaching paper pulp. A. D. MERRILL. U. S. 1,556,235, Oct. 6.

Tough long-fibered paper impregnated with rubber. K. L. MOSSES. Brit. 230,994, March 22, 1924.

Coating paper with nitrocellulose compositions containing metal powder. J. MARSHALL. Brit. 231,180, March 18, 1924.

Deinking paper. E. KELLNER. U. S. 1,555,674, Sept. 29. Waste paper to be reworked is pulped at about 75°, treated with Na_2CO_3 , heated to about 90° and mixed, then treated with "chloride of lime" and S, again heated for a short time and washed.

Apparatus for recovery of values from waste waters of paper manufacture. V. ANTOINE. U. S. 1,554,943, Sept. 22.

Paper-making apparatus. R. S. CLARKE. U. S. 1,552,594, Sept. 8.

Translucent film. C. H. DASHER. U. S. 1,552,422, Sept. 8. Films adapted for making bottle caps, artificial flowers, etc., are formed of cellulose regenerated from viscose mixed with cementing viscose.

Lignone derivatives. C. F. CROSS. U. S. 1,553,220, Sept. 8. Sol. lignone derivs obtained by treatment of lignocellulosic materials with SO_2 are treated with an oxidizing agent such as chromic acid to produce substances which may be used for sizing or filling wood. Cf. C. A. 19, 1348.

Carbon pigment. S. F. WALTON. U. S. 1,552,973, Sept. 8. The black ash residue of the soda process of wood pulp manufacture is treated, e. g., by sedimentation and flotation in H_2O , to remove the lighter and heavier portions and leave a carbonaceous residue which is then ground to form a pigment.

24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

Nephelometry, and a suggested sensitive test for the stability of explosives. A. F. C. POLLARD. *Trans. Opt. Soc.* 26, 63-73(1924-5); *J. Soc. Chem. Ind.* 44, 614B. The rate of decompn. of propellent explosives at atm. temp. is measured by sweeping off the accumulated N peroxides with a current of air. This air is to be passed through a colloidal soln. of Ag_2O contained in one tube of a Kingslake nephelometer (*Trans. Optical Soc.* 26, 53-63), and the disappearance of the colloidal particles due to the action of the N peroxides is followed by the reduction of the scattered light, the amt. of which is measured by the movement of the standard tube necessary to restore optical equality in the photometric field. The tests are carried out at intervals not exceeding 10 hrs., the amt. of N peroxide accumulated during the interval being thus measured.

CHARLES E. MUNROE

Connecting blasting caps with fuse. M. LUPUS. *Z. ges. Schiess-Sprengstoffw.* 20, 116-7(1925).—A description of a patented connector which eliminates danger in crimping caps onto fuse with the usual type of crimper.

C. G. S.

Explosions of hydrogen-oxygen mixtures. W. NORMANN. *Chem.-Ztg.* 49, 757 (1925).—An electrolytic O_2 plant found that the delivery pipes had been crossed and the gases mixed. No accident occurred because the error was discovered in time. Tests were then made to det. the effectiveness of wire gauze in preventing flash-back. A small gasometer was filled with a 2:1 mixt. of H_2 and O_2 and the gas delivered through a small flask filled with H_2O to a Fresenius tube 1 cm. wide, 6 cm. long, in the center of which were a number of Cu gauze screens fitting the side walls closely. This safety tube is effective with a H_2 -air mixt., but only prevented flash-back with H_2 - O_2 mixts. when a certain velocity was not exceeded, this velocity depending upon the fineness of the gauze. It is therefore not a dependable safety device for this purpose.

E. M. SYMMES

The initiation of explosives. OTTO SCHULZE. *Z. ges. Schiess-Sprengstoffw.* 20, 113(1925).—Expts. showed that direct contact of elec. detonators or blasting caps with dynamite charges is not essential for complete detonation of such charges. A charge of 100 g. of 60% nitroglycerin dynamite was loaded in an Fe pipe 25 mm. diam., 75 mm. long and 3 mm. thick, capped at its bottom end, the pipe filled with water, and a No. 8 detonator exploded in the water. The dynamite detonated with the detonator at a distance of 40 cm. The pipe was bulged opposite the position of the detonator and demolished at its lower end by the explosion. When the water was replaced by air detonation occurred with a still greater gap between the dynamite and the detonator (55 cm.), and in a vacuum the max. effective distance was 40 cm. With less sensitive explosives or with weaker detonators, detonation was obtained only at shorter distances, e. g., with an NH_4NO_3 explosive contg. 4% nitroglycerin, the effective gap in water was reduced to 2 cm., even with a No. 8 detonator.

C. G. STORM

Detonation limits in explosive gas mixtures. RUDOLF WENDLANDT. *Z. physik. Chem.* 116, 227-60(1925); cf. *C. A.* 18, 3115.—Detonating reactions are characterized by high condensation behind the flame and a high velocity of propagation. In long tubes the velocity of detonation is independent of the length of the path, the materials used for the walls of the tube, the cross section of the tube, etc., but is characteristic for each mixt. Upon diluting a detonating mixt. the velocity of detonation finally suffers a sudden decrease at a certain diln. Thus in a H_2 -air mixt. such a crit. condition occurs with the H_2 content between 18 and 19%. This is due to the relationship of pressure, time necessary for reaction, temp., cond. of the gases concerned, etc. A thermodynamic theory of limiting conditions is based upon the work of Riemann-Hugoniot, Jouguet, Le Chatelier, Dixon and others; exptl. results for mixts. of H_2 -air, CO-air, CO_2 and other detonating gases are assembled, plotted and discussed; and illustrations are given of the ways in which the equations and data can be employed in calcs., affording information concerning even regions that cannot be studied by exptl. methods.

W. C. EBAUGH

The influence of some inflammable vapors of organic liquids on the limits of inflammability of mixtures of inflammable gases and air. IV. The influence of dichloro- and trichloroethylene on the limits of inflammability of carbon monoxide-air mixtures. W. P. JORISSEN AND J. H. A. P. LANGEN VAN DER VALK. *Rec. trav. chim.* 44, 810-3 (1925). (In English).—Previous results (J. and Meuwissen, *C. A.* 19, 2274) showed that $(CHCl)_2$ lowered both explosion limits of mixts. of NH_4 + air, CO + air, C_2H_2 + air and H_2 + air. This paper is an extension of the CO + air expts. Air satd. with $(CHCl)_2$ was stored in a thermostat and used to make the mixts. The upper and lower explosion limits of CO + air at 14° in the modified app. were 15.35 and 72.72%, resp. With 5% $(CHCl)_2$ vapor the limits were 6.65 and 50.25%; with 10% $(CHCl)_2$ vapor 1.8 and 27.8%; with 12% 1.95 and 16.5%; with 14% 0.75 and 7.6%; with 16% 1.75 and 3.7%. The final limit was found at 16.6% $(CHCl)_2$ vapor and 2.5% CO which were the limiting concns. of explosibility of both components. With 2% $CHCl_3$ vapor and CO + air the upper and lower limits were 18.95 and 52.75%, resp. With 3% $CHCl_3$ the upper limit was 43.55%, lower limit not detd.; with 4% the lower limit was 21.45%, upper limit not detd. Similar data are being developed with CH_2Cl_2 , $MeCl$ and CH_4 . The expts. demonstrate the importance of an investigation on the possible explosion limits of so-called noninflammable liquids and the influence of small amts. of inflammable gases on these limits. V. The influence of trichloroethylene on the limits of inflammability of hydrogen-air mixtures. W. P. JORISSEN AND B. L. ONG-KUOHONG. *Ibid* 814-7.—Previous expts. (*C. A.* 19, 2274) showed that the upper and lower explosion limits of H_2 + air mixts. can be lowered by C_2HCl_3 . The expts. were extended. With H_2 + air alone the limits were 6.3 and 61.3% at 14° ; with 3% C_2HCl_3 vapor they were 5.9 and 43.3%; with 6.05% C_2HCl_3 (satd. vapor) the limits were 4.9 and 25.9%. With H_2 + air alone the limits were 5.9 and 62.3% at 25° ; with 3% C_2HCl_3 the limits were about as at 14° ; with 5% C_2HCl_3 the limits were 5.1 and 42.9%; with 10.84% C_2HCl_3 (satd. vapor) the limits were 5.1 and 20.8%. With H_2 + air alone the limits were 6.1 and 63.1% at 35° ; with 3% C_2HCl_3 6 and 47.2%; with 6% C_2HCl_3 4.7 and 41.1%; with 10% C_2HCl_3 4.2 and 34.9%; with 14% C_2HCl_3 6.7% was the lower limit; with satd. C_2HCl_3 vapor (15.7%) no explosions were obtained with 4.0 to 20.0% H_2 . The ratio of H_2 to O_2 was calcd. for all of the expts. and also shows the lowering of the lower explosion limit by C_2HCl_3 vapor. The lowering of the lower limit increases with the temp. Other work of this sort is underway.

E. J. WITZEMANN

Gaseous combustion at high pressures. V. The explosion of H-air and CO-air mixtures at varying initial pressures up to 175 atmospheres (BONE, *et al.*) 21. Isopropyl aromatic amines [for stabilizing explosives] (U. S. pat. 1,555,451) 10.

Explosive. J. EHRLICH. U. S. 1,550,064, Aug. 18. The Na salt of sulfanilic acid or other salt of an org. aminosulfo acid is used with other components of explosives such as oxidizing salts or nitro compds.

Liquid air explosive. G. WEBER. U. S. 1,555,806, Sept. 29. Liquid air is used with a combustible metal powder such as Al, Sb, Mg, Fe, Si or silicides and with inert and combustible absorbent substances such as cork flour, saw dust, soot and hydrocarbons.

Propellant explosive powder. J. B. FIDLAR AND C. R. FRANKLIN. U. S. 1,552,601, Sept. 8. Nitrocellulose is used together with a colloiding explosive such as nitroglycerin, hydrocellulose and a stabilizer, *e. g.*, urea or diphenylamine.

Furnace for burning explosive charges from fuses and percussion caps of artillery ammunition. G. ALLISON. U. S. 1,549,896, Aug. 18.

Priming composition. W. FRIEDERICH. U. S. 1,552,836, Sept. 8. A priming mixt. suitable for general use with explosives is prepd. by slowly pouring solns. of alkali metal azides and of alkali metal salt forming nitro compds., such as Na azide and Na picrate, into solns. of Pb salts such as Pb nitrate.

Smoke material for "sky writing." J. C. SAVAGE. Brit. 231,826, April 3, 1924. A material for producing red smoke comprises 10 lbs. of orange oil sol. aniline dye, 1 gal. of light mineral lubricating oil and 1 pint of $C_2H_2Cl_4$ or CCl_4 . For green smoke, the orange oil sol. aniline dye is mixed with synthetic indigo. It is used for purple smoke and "anthracene" for black or gray smoke.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

The science of dyeing. H. F. HEERMANN. *Proc. Am. Assoc. Textile Chem. Colorists* 1925, 187-90; *Am. Dyestuff Rept.* 14, 659-62; cf. C. A. 19, 896.—The functions of chromophores and chromogens in the formation of dyes are discussed. L. W. R.

Dyeing of artificial silk. E. K. PALMER. *Ind. Chemist* 1, 133-6(1925).—Details are given for the manuf. of the different kinds of artificial silk, and for the special precautions to be observed in dyeing these fabrics. L. W. RIGGS

Cotton dyeing. R. K. PALMER. *Ind. Chemist* 1, 398-9(1925).—The general characteristics of direct cotton colors, vat dyestuffs, sulfur colors, basic colors, azo colors, primuline red and the ingrain colors, aniline black and the mineral colors are described, and the usual methods of application to cotton outlined. The equipment employed and the plant methods employed for loose dyeing, silver dyeing, yarn dyeing and piece dyeing are briefly dealt with. E. G. R. ARDAGH

Swelling of raw cotton hairs during mercerization without tension. MARY A. CALVERT and FREDERICK SUMMERS. *J. Textile Inst.* 16, 233-68T(1925).—The unit of mercerization is the single cotton hair, a plant product of great variability. The relation between the mercerized and unmercerized hair width was examd. in 38 world cottons and the results are shown in 23 tables. The cuticle of the hair sets a limit to the amt. of swelling in the outward direction. L. W. RIGGS

"Lanolinification" of cotton, permanent dressings. ED. JUSTIN-MUELLER. *Bull. soc. ind. Mulhouse* 91, 399-400(1925); Sealed Note 2221 of Jan. 1, 1913.—"Lanolinification" is a treatment giving to cotton the feel of wool and the permanent stiffness of flax fibers, consisting in impregnating the dyed, bleached or merely boiled fiber (yarn or fabric) with a soln. of albumin contg. a sol. oil, paraffin or stearin with a suitable solvent, and CH_2O , letting stand overnight in a moist condition, steaming 15-20 min. without previous drying, passing through a bath of an Al salt, rinsing, washing and drying. Steaming fixes the albumin, and the CH_2O gives a much softer feel, like that of wool. Report. JACQUES LEONHART. *Ibid* 400-1.—L. found the above treatment to give the feel of flax, but did not observe the action claimed for CH_2O . Sol. oil and paraffin, rather than CH_2O , gives a soft feel. The process is not applicable to white goods, as they yellow on steaming. The process cannot compete commercially with Heberlein & Co.'s concd. H_2SO_4 process, evolved during the war. A. P.-C.

New process of dyeing wool with alizarin black WX extra. RENÉ HARTMAN. *Bull. soc. ind. Mulhouse* 91, 402-3(1925); Sealed Note No. 1706 of Feb. 9, 1907.—The soly. of the dye is increased by adding $NaHSO_3$, and HCO_2H is added to obtain proper exhaustion of the bath without deterioration of the fiber or excessive decomposition of the $NaHSO_3$. The HCO_2H required for complete exhaustion of the dye bath increases with the amount of $NaHSO_3$ which must be added to dissolve the dye. Process for dyeing with alizarin black WX extra. Sealed Note No. 1712 of Feb. 28, 1907, *Ibid* 404-5.—Improved fastness to rubbing and more complete exhaustion of the dye bath are obtained by using $(NH_4)_2SO_4$ instead of $AcOH$ and Na_2SO_4 in the dye bath. Report. VERNIER. *Ibid* 405-6.—V. was able to confirm H.'s claims, and could find no priority. A. PAPINEAU-COUTURE

Some causes of staining of woollen goods. H. LAGACHE. *Tiba* 3, 909-17(1925).—A discussion of the effects of air, light, acids, alkalis, yeasts and molds, and frost on wool, from the standpoint of staining during dyeing or finishing. A. P.-C.

Removal of stains and spots in finished goods. T. JOHNSON. *Am. Dyestuff Rept.* 14, 664-5(1925).—Stains are caused (1) by dirty app., (2) by action of solns. on

metals or wood used in the construction of app., (3) by water conditions, particularly hard water. Procedures for avoiding stains are emphasized. L. W. RIGGS

Bleaching agents. R. BÜRSTENBINDER. *Seifensieder Ztg.* 52, 655-6(1925).—Polemical against Heermann (cf. *C. A.* 18, 3485) in regard to O_2 -contg. bleaching agents for laundrying. P. ESCHER

The fading of colored materials by daylight and artificial light. M. LUCKIESH AND A. H. TAYLOR. *Am. Dyestuff Rept.* 14, 613-8, 637(1925).—The effect of various factors, such as illumination intensity, spectral character of the radiation, temp., humidity, etc., were studied with silk ribbons. The av. results of tests on 23 ribbons show that exposure to sunlight and skylight at 3900 foot-candles for 11 hrs., or to skylight alone at 450 foot-candles for 40 hrs., will cause as much fading as exposure to 500 foot-candles from tungsten lamps for 100 hrs. Also that approx. equal degrees of fading will result from exposures to W filament radiation for 100 foot-candle-hrs., skylight for 34 foot-candle-hrs., or sunlight and skylight combined for 77 foot-candle-hrs. L. W. R.

Isopropyl aromatic amines [for making dyes] (U. S. pat. 1,555,451) 10. Isopropyl-*p*-aminophenol [for dyeing furs] (U. S. pat. 1,555,452) 10.

Dyes. E. B. HIGGINS and BRITISH SYNTHETICS, LTD. Brit. 230,920, Dec. 19, 1923. Amides of *o*-hydroxycarboxylic acids, such, *e. g.*, as the product obtainable from the di-Na or K salt of 2,3-hydroxynaphthoic anilide by treatment in alc. with pyridine methyl iodide, yield azo dyes when coupled with diazo compds. either in substance, on substrata or on the fiber. Various examples are given.

Dyes. FARBENFABRIKEN VORM. F. BAYER & Co. Brit. 231,532, March 31, 1924. Dyes giving yellow to red shades on cotton from a vat are prepd.: (a) by nitrating a dianthraquinonyl diamide such as di- α - or β -anthraquinonyl-urea or -succindiamide, reducing and aroylating; (b) by condensing an α -nitroaminoanthraquinone (2 mols.) with a dibasic acid or its anhydride or chloride, reducing and aroylating; (c) condensing an α -aroylaminoaminoanthraquinone (2 mols.) with a dibasic acid, etc.; (d) condensing an α -aroylaminoanthraquinonyl-monoamide of a dicarboxylic acid with an aminoanthraquinone; (e) condensing 1 mol. of a dibasic acid dichloride first with 1 mol. of an α -aroylaminoaminoanthraquinone and then at a higher temp. with 1 mol. of a second α -aroylaminoaminoanthraquinone. Specific examples are given.

Dyes. SOC. ANON. POUR L'IND. CHIM. A. BÂLE. Brit. 231,688, May 6, 1924. Aminoanthraquinone derivs. which dye vegetable fiber from the vat orange to brown or olive shades are produced by further condensation, with other substances, of the condensation product made by condensing 2 mols. of cyanuric chloride with 1 mol. of 1,5-diaminoanthraquinone or 1,8-diaminoanthraquinone or a mixt. of both. Numerous examples are given.

Dye. SOC. ANON. POUR L'IND. CHIM. A. BÂLE. Brit. 231,555, Nov. 29, 1923. A dye, dyeing cotton from a vat in green-blue shades fast to Cl, is made by caustic alkali fusion of 2-aminoanthraquinone-3-carboxylic acid, which may be carried out in the presence of an "organic flux" such as alc., paraffin oil, aniline, xyldine or anisidine and then purifying the product, *e. g.*, by dissolving in strong H_2SO_4 and reprecip., or by other specified purification methods. Brit. 231,574 specifies producing the dye by treating 2-aminoanthraquinone-3-carboxylic acid with an oxidizing agent (*e. g.*, with MnO_2 and H_2SO_4) and purifying the product as in Brit. 231,555.

Dyes. SOC. ANON. POUR L'IND. CHIM. A. BÂLE. Brit. 232,251, April 9, 1924. Bordeaux to blue and black azo dyes are formed, in substance or on the fiber, by coupling tetrazotized diaminoazo compds. with 4-hydroxynaphthalene-1-aryl-ketones. Numerous examples are given.

Dyes. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING. Brit. 232,230, April 9, 1924. Dyes of the symmetrical indigoid type which produce red to violet shades on cotton are made: (1) by heating an α -anil of a substituted 2,3-diketodihydrothionaphthene with a substituted arylthioglycol-*o*-carboxylic acid in the presence of Ac_2O , with or without a diluent; or (2) by condensing (with or without a diluent) an acylated oxythionaphthene, made by treating an arylthioglycol-*o*-carboxylic acid with Ac_2O , with an α -anil of a 2,3-diketodihydrothionaphthene. Numerous examples are given.

Dyes. FARBWERKE VORM. L. DURAND, HUGUENIN & Co. Brit. 231,889, April 4, 1924. Esters of leuco compds. of vat dyes (*e. g.*, leuco thioindigo red) are treated with chlorosulfonic alkyl esters (*e. g.*, the Et or Me ester in the presence of pyridine). The products are in general less sol. and more readily isolated than the acid sulfuric esters described in Brit. 186,057 (*C. A.* 17, 343).

Dyes. H. PEREIRA. Brit. 232,262, April 10, 1924. Perylene or its derivs., *e. g.*, dibenzoylperylene, is heated with a P sulfide, preferably in the presence of a diluting agent such as kieselguhr. On oxidation the products yield other dyes of a sulfonic character and on treatment with S and a sulfide S dyes are obtained. Green, red and orange colors are produced on cotton or wool by various of the specified dyes.

Dyes. H. PEREIRA. Brit. 232,263, April 10, 1924. Vat dyes are prepd. by heating nitro derivs. of perylene with anhyd. AlCl_3 . Dinitro- and tetranitro-perylene both yield dyes producing olive shades on cotton. Dinitroperylene is obtained by treating perylene dissolved in CCl_4 with HNO_3 without heating.

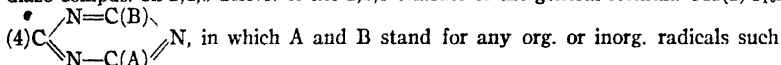

Dyes. H. PEREIRA. Brit. 232,265, April 10, 1924. In the condensation of dibenzoylperylene or other perylene compds. by the use of AlCl_3 , oxidizing agents such as MnO_2 , Fe_2O_3 , FeCl_3 , Cu oxide, KNO_3 and Ni sulfate are added to alter the character of the dye produced or to increase the yield obtained. Numerous examples are given.

Dyes. H. PEREIRA. Brit. 232,266, April 10, 1924. Perylene is halogenated by the action of halogen in the nascent state, *e. g.*, H_2O_2 is slowly added to a suspension of perylene in glacial HOAc contg. Na bromite, to form a dibromo compd. which is pptd. and can be recrystd. from PhNO_2 . Vat dyes dyeing cotton yellow to brown are obtained by various similar reactions which are described.

Azo dyes. H. WAGNER. U. S. 1,549,822, Aug. 18. Various diazo compds. are combined with 2,3-hydroxynaphthoic acid anilide in which the anilide ring is substituted in the 2-position by halogen and in the 5-position by alkyloxy, aryloxy or aralkyloxy groups. Numerous examples are given.

Azo dyes and lakes. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING. Brit. 231,529, March 29, 1924. Azo dyes are produced, either in substance or in the form of lakes or upon the fiber, by coupling with 2,3-hydroxynaphthoic arylides the diazo compds. of 2-amino-4-arylamino-1-alkyloxy- or -aralkyloxy-benzenes not contg. a free hydroxyl, sulfonic or carboxylic group, *e. g.*, 2-amino-4-benzoylamino-1-anisole and its derivs. Cf. C. A. 19, 3024.

Triazine azo dyes. G. BONHOTE. U. S. 1,549,901, Aug. 18. Dyes are formed by the reaction of diazotized 4-chloro-2-aminobenzene-1-phenyl ether or other unsulfonated diazo compds. on 2,4,6-derivs. of the 1,3,5-triazine of the general formula $\text{OH}(1)\text{C}_6\text{H}_6$,

OH or NH_2 . Dyes giving yellowish red to blue and black are obtained.

Disazo dyes. FARBENFABRIKEN VORM. F. BAYER & Co. Brit. 231,885, April 4, 1924. Disazo dyes are produced by coupling diazotized *m*-aminobenzeneazosalicylic acid or homologs or derivs., with 1-acidylamino-8-naphtholsulfonic acids. They may be used for printing red shades on cotton with Cr acetate. The *m*-aminobenzeneazosalicylic acids are prepd. by coupling diazotized *m*-nitroanilines or acidyl-*m*-phenylene diamines with salicylic acids and reducing or saponifying.

Thioindigoid dyes. FARBWERKE VORM. MEISTER, LUCIUS & BRÜNING. Brit. 231,567, Dec. 22, 1923. Thioindigoid dyes are produced by halogenating the 2,3,2',3'-bisanaphthothiophene-indigo or the dyes made by condensing 2,3-naphthoxythiophene with reactive α -derivs. of isatin, or by use of suitable components one or more of which contains a halogen. Numerous examples are given. Cf. C. A. 19, 1058.

Chromium compounds of dyes. SOC. ANON. POUR L'IND. CHIM. A BÂLE. Brit. 231,446, March 28, 1924. Cr compds. of dyes, which dye wool fast levelling tints, are made by interaction of a triphenylmethane dye which can be chromed (*e. g.*, Eriochromazurol B, Eriochromcyanine R or Chrome violet) and a Cr compd. of an azo dye which can be chromed, *e. g.*, the Cr compds. of the azo dye from 1-amino-2-hydroxynaphthalene-4-sulfonic acid and α - or β -naphthol. These compds. may be formed directly on the fiber.

Dyes for cellulose acetate, etc. R. TONKIN, J. THOMAS, E. G. BECKETT AND SCOTTISH DYES, LTD. Brit. 231,206, Sept. 14, 1923. The diphthalimidoanthraquinones described in Brit. 214,765 (C. A. 18, 2715) are nitrated, the products are hydrolyzed and treated with alkali metal sulfide, to produce dyes which appear to be hexaamino-dianthraquinonylthioethers which dye cellulose acetate or wool blue.

2-Amino-1-hydroxynaphthalene-8-sulfonamide-4-sulfonic acid. SOC. ANON. POUR L'IND. CHIM. A BÂLE. Brit. 231,149, March 20, 1924. 1,8-Naphthsultone is sulfonated, nitrated or nitrosated, treated with NH_3 and then reduced. Its diazo compd., when coupled with other usual components, yields mordant dyes which may be converted into sol. metal compds. with Cr or Cu compds. The products dye wool

orange, brown, red, blue, violet, etc. and may be used in printing. Numerous examples are given.

Condensation products from hydroxybenzenesulfonic acid. P. VIRCK. U. S. 1,553,014, Sept. 8. Colorless compds. contg. S and capable of being absorbed by textile fibers for use as mordants for basic dyes are obtained by heating a hydroxybenzenesulfonic acid with a resinous product produced by the action of S chloride on a hydroxybenzene, *e. g.*, phenol.

Dyeing. A. ESCHACH and J. P. WORMS. Brit. 231,209, Oct. 22, 1923. Animal or vegetable fibers are dyed by oxidizing phenols, amines or their salts by the action of persulfate together with a metallic salt or oxide. Numerous examples are given of processes producing different colors.

Dyeing. DURAND ET HUGUENIN SOC. ANON. Brit. 231,189, March 20, 1924. In dyeing cotton, mercerized cotton, viscose or other textile material with esters of leuco vat dyes as described in Brit. 186,057 the affinity of the fiber for the esters is increased by adding a salt such as NaCl or Na₂SO₄ to the bath.

Dyeing apparatus. C. JENSEN. U. S. 1,555,673, Sept. 29.

Printing cellulose acetate. SOC. ANON. J. R. GEIGY. Brit. 231,897, March 31, 1923. Aromatic sulfonic or carboxylic acids or their salts are added to the printing paste, or the cellulose acetate goods are impregnated with these compds. before being printed. A printing paste may, *e. g.*, comprise setoglausine, 2-naphthol-7-sulfonic acid, HOAc and a gum thickening. Various sulfonic acids of benzene, naphthalene or anthraquinone, or salicylic acid, or oxy-, alkyl-, chloro- or nitro- derivs. of these may be used. Cf. C. A. 18, 2433.

Dyeing cellulose acetate. SOC. ANON. POUR L'IND. CHIM. A BALE. Brit. 231,455, March 31, 1924. Cellulose acetate goods are dyed violet, green, blue and black shades with mono azo dyes contg. one or more diazotizable amino groups, the shades being diazotized and developed with alkyl- or aralkyl- α -naphthylamines. Numerous examples are given.

Dyeing cellulose acetate. R. CLAVEL. U. S. 1,549,906, Aug. 18. In dyeing films, artificial silk, etc., of cellulose acetate, at least one of the components to be coupled, *e. g.*, dianisidine-HCl, is applied in the presence of MgCl₂ or other sol. chloride and of a protective colloid, *e. g.*, gelatin, soap or "boiled-off liquor" which serves to prevent pptn.

Titanous salts for use in dyeing, etc. S. F. W. CRUNDALL, W. B. LLEWELLYN, H. SPENCE, and P. SPENCE & SONS, LTD. Brit. 230,877, Oct. 11, 1923. Citric, tartaric, oxalic, lactic, or succinic acid, Na or Ca citrate, Na oxalate or other org. acid or salt is added to a titanous salt of an inorg. acid during its use in soln. for stripping or discharging dyes. The org. acids may be partially substituted for the inorg. acid in prep. the soln. and the soln. may be concd. until it becomes solid or semi-solid on cooling. Al₂(SO₄)₃ facilitates the solidification.

Apparatus for dyeing and scouring yarn, etc. J. BOARDMAN AND HUNT & MOSCROP, LTD. Brit. 230,954, Jan. 19, 1924.

Apparatus for dyeing and scouring wool, etc. J. BOARDMAN, E. W. HUNT AND HUNT & MOSCROP, LTD. Brit. 230,953, Jan. 19, 1924.

Apparatus for dyeing or scouring yarn in hanks or skeins. H. M. DUDLEY. U. S. 1,555,837, Oct. 6.

Duplex apparatus for dyeing warps on beams. B. K. THIES. Brit. 232,494, Sept. 18, 1924.

Artificial silk. A. KÄMPF. Brit. 232,200, April 12, 1924. Viscose silk or the like, especially that made from unripened alkali cellulose, is subjected to a vacuum treatment for removing CS₂, before the usual washing and immediately after spinning.

Artificial silk. R. FRANKL. Brit. 232,219, April 10, 1924. Mech. features of "drawing-out" of threads spun from viscose solns. into an acid sulfate soln. contg. free acid.

Artificial silk from viscose. W. J. STEVENSON. U. S. 1,556,174, Oct. 6. See Brit. 225,135 (C. A. 19, 1952).

Apparatus for forming artificial silk. C. SANDOZ. Brit. 232,482, Aug. 29, 1924.

Washing artificial silk. H. LUMMERZHEIM. U. S. 1,553,252, Sept. 8. Spools of artificial silk are subjected to a relatively short preliminary washing with H₂O forcibly applied mechanically and then immersed for a longer time in a body of H₂O which is renewed until the washing is completed.

Waterproofing fabrics. A. H. PENFIELD. U. S. 1,549,798, Aug. 18. After washing threads, yarn or similar material with soap soln., it is subjected to the action of an

elec. current in a soln. of $Al_2(SO_4)_3$, freed from surplus soln. and dried at about 70–80° before being woven into fabric.

Waterproofing composition. W. F. CRAWFORD. U. S. 1,554,715, Sept. 22. A compn. for waterproofing and mildewproofing textile materials is prepd. by mixing paraffin, wool grease, linseed oil, coloring material and gasoline and heating the mixt. to the b. p. during mixing.

Waterproofing compositions. E. GERMANN. Brit. 231,367, July 10, 1924. A compn. for application when melted to waterproof and color textile fabrics, etc., comprises ceresin, stearic acid, paraffin, japan wax and fat, mixed with a mineral pigment. Wool grease treated with Al acetate may be used, as may also tallow and rosin.

Silky and elastic finish on vegetable fabrics. L. LILIENFELD. Brit. 231,804, April 4, 1924. Cotton or other vegetable fabrics are treated with a halohydrin and with an alkali, e. g., with α -monochlorohydrin, epichlorohydrin or ethylene chlorohydrin and with NaOH. Numerous details and statements of auxiliary treatments are given.

Imparting luster and stiffness to vegetable fabrics. L. LILIENFELD. Brit. 231,803, April 4, 1924. Fabrics made of vegetable fiber are stiffened or given a silky luster (or both) by simultaneous or successive treatment with alkali (e. g., a 10–40% NaOH soln.) and with monochloroacetic acid, α -bromopropionic acid, α -bromobutyric acid or bromosuccinic acid or a similar monohalogen fatty acid. The materials may be given a preliminary treatment, e. g., by boiling with dil. alkali soln., bleaching or mercerizing or by treatment with a gelatinizing or hydrolyzing agent such as strong inorg. acid, ammoniacal Cu oxide or thiocyanate solns.

Composition for finishing textile materials. J. F. MOSELEY. U. S. 1,554,919, Sept. 22. A mixt. comprising bentonite and $MgSO_4$ or other neutral sulfate is used for finishing, together with china clay and starch or other usual filling materials.

Scouring and bleaching textile materials. E. T. J. WATREMEZ. Brit. 231,454, March 28, 1924. Ordinary scouring or bleaching agents such as NaOH or NaOCl solns., used on cotton, linen or other cellulosic materials, are mixed with a soln. obtained by dissolving a metal oxide such as Al_2O_3 in a hot concd. soln. of an alk. salt such as Na_2CO_3 .

Bleaching animal, vegetable and artificial fibers. C. PHILIPP, R. FEIBELMANN and R. HALLER. U. S. 1,554,461, Sept. 22. The fibers are treated with a salt of an aromatic sulfohalogenamide, e. g., chloramine-T.

Batik. M. SCHLOZ. U. S. 1,553,721, Sept. 15. See Brit. 214,507 (C. A. 18, 2610).

Composite yarns of wool and flax. SOC. A. DESCAMPS. Brit. 231,432, March 27, 1924.

Apparatus for bleaching textile materials with ozone. F. E. HARTMAN and H. B. HARTMAN. U. S. 1,553,042, Sept. 8.

Mercerizing yarns. L. A. STREAD. U. S. 1,554,532, Sept. 22. Mech. features

Apparatus for mercerizing yarn. T. MCCONNELL. U. S. 1,555,864, Oct. 6.

Yarn-sizing apparatus. G. F. SLIPP. U. S. 1,553,403, Sept. 15.

26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

Chemical Foundation patents on liquid coating compositions. H. A. GARDNER. Paint Manufs. Assoc. of U. S., *Circ.* No. 249, 75–88(1925).—A list by name, title number, and first claim, of all patents in the liquid coating compn. group owned by the Chem. Foundation, Inc., and available for license to Am. manufs. F. A. WERTZ

The painting of ships. R. G. BROWNING. *J. Oil and Colour Chem. Assoc.* 8, 173–81(1925).—An historical review of the use of anti-fouling and anti-corrosive compns., and of the general paint requirements of ships. F. A. WERTZ

Suggestions relating to paste paint compositions and reductions. H. A. GARDNER. Paint Manufs. Assoc. of U. S., *Circ.* No. 245, 51–3(1925).—Pigment concn. in the film plays a very important part in the durability of paints. In reducing paste paints it is, therefore, desirable to use the proper liquids: too much oil and lack of proper driers will produce soft, dirt-collecting films; a high percentage of volatile thinner produces a more durable paint in hot, moist climates. F. A. WERTZ

A pigmented non-drying rust protective for temporary work. H. A. GARDNER. Paint Manufs. Assoc. of U. S., *Circ.*, No. 246, 54–8(1925).—A pigmented slushing compd. consisting of heavy petrolatum 50 lbs., Zn dust 30 lbs., Al powder 2 lbs., mineral

spirits 5 lbs. has the advantage that its more rigid consistency makes it less subject to sagging at high temp.; the Zn content affords added protection; and the Al adds brilliancy and good appearance. Abstracts of the specifications for clear rust preventive compds. of the Federal Specifications Board are appended. F. A. WERTZ

Wood fillers and undercoatings. SEDLACZEK. *Farben-Ztg.* 30, 2796-8, 2865-6 (1925).—A review of patented and other formulas. F. A. WERTZ

Casein in the decorative painting of walls. HUGO KÜHL. *Farben-Ztg.* 30, 2629-30 (1925).—Review. F. A. WERTZ

Driers. FELIX WILBORN. *Farben-Ztg.* 30, 2665-7 (1925).—Review. F. A. W.

Driers. H. RASQUIN. *Farben-Ztg.* 30, 2603-4 (1925).—A summary of a thesis on the action of driers in the manuf. of oil varnishes, FERD. PALLAUF, Tech. Hochschule München (1924). The drying of linseed oil occurs through autoxidization. The increase of drying properties imparted to an oil on mixing with metallic oxides occurs only after the formation of soaps. Preference for metallic linoleates or resinates lies largely on their solys. Only insignificant differences were shown in the drying strength of Co linolenate, linoleate, oleate, and palmitate; Pb linolenate was not as effective as the oleate, and the palmitate was decidedly poorest because of its lower soly.; the Mn soaps were ranked in the same order.¹ Tungstates are not as practical driers as linoleates or resinates. Drying time plotted against the amt. of drier present produces a hyperbolic curve. On varnishes contg. Co, Pb, Pb-Mn, or Mn driers, the drying time decreased by almost exactly half for each 10° increase in temp. detd. over the range 0-50°. The metals in decreasing order of drying effectiveness are Co, Mn, Ce, Pb, Fe, Cu, Ni, V, Cr, Ca, Al, Cd, Zn, Sn. The final increase in wt. on drying of oils contg. Pb, Mn, or Co driers is essentially the same, but the induction period varies. The concn. of Pb-Mn for optimum drying should not exceed 0.6% and in the proportion of Pb:Mn = 3:8:1. In the manuf. of boiled oil the use of PbO is preferred to Pb₂O₄ or PbO₂. The decreased drying properties of old varnishes occur through pptn. of the driers. Some graphs are given. F. A. WERTZ

Possible production of titanium white from Canadian sources. H. A. LEVERIN. *Can. Chem. Met.* 9, 198-9 (1925).—A brief review of the American and Norwegian processes for making Ti pigment, and of its properties, is given. The ilmenite deposits in the Provinces of Que. and Ont. contain 34 to 44% TiO₂; this is somewhat lower than the ores used in the U. S. Typical analyses are given. A recently developed process which promises to produce Ti white at a low price consists in reducing the ore to sponge Fe. Most of the Fe is then leached out with FeCl₃ and the resultant FeCl₂ is used to produce electrolytic Fe. The residue consists of 77 to 80% TiO₂, 7 to 10% Fe, and the remainder gang; this is treated with H₂SO₄ for the ultimate production of Ti white. F. A. WERTZ

Universal colors for the paint industry. MARTIN SEIDEL. *Chem.-Ztg.* 49, 697-8 (1925).—Attempts have been made to reduce the no. of pigments necessary to produce a complete variety of paints in all colors, by the adoption of a series of 10 to 12 "universal" pigments based on the fundamental spectral colors. Such pigments must be lime-proof, H₂O-proof, non-bleeding in oil, and permanent to light. Examin. of several com. universal pigment series showed that they failed in certain requirements; a suggested series which does comply with the requirements consists largely of org. toners and lakes, whose present prices prohibit their general com. use. F. A. WERTZ

The drying of materials in the color industry. REHNUS. *Farben-Ztg.* 30, 2477-80, 2553-4, 2608-11, 2741-3, 2809-10 (1925).—A brief general description of the operation of filter presses, centrifuges, driers, etc. F. A. WERTZ

Lithopone. A. EIBNER. *Farben-Ztg.* 30, 2600-2 (1925).—An historical review of the gradual improvement in the light resistance of lithopone which has accompanied a decrease in the impurities present. F. A. WERTZ

Other-soluble sulfur in ultramarine. T. H. BARRY. *J. Oil and Colour Chem. Assoc.* 8, 202-4 (1925).—The quantities of free S in a large no. of European ultramarines of all possible colors, detd. by extn. with Et₂O, are tabulated; and the color measurements on the extd. pigment are compared with the original. The free S in ultramarines of good quality is invariably less than 1%, and it does not appear to have any material influence on the color or the permanency of the pigment, but quantities in excess of 1% may possibly have some effect. Re-extg. samples after 2 yrs. shows no further S, so that it appears that S is not liberated from ultramarine during storage. Cf. C. A. 14, 635. F. A. WERTZ

Unproductive use of the German chamber method in most white lead works. GUSTAV ARNOLD. *Chem.-Ztg.* 49, 594-5 (1925).—The production of highest grade basic carbonate white lead which is as free as possible from the normal carbonate requires

the production of a true basic Pb acetate as the initial step in the process. This is not accomplished in most chamber processes because of failure to observe proper concns. of AcOH, temps., etc. The vapors of not to exceed 6% AcOH should be led into the chamber with plenty of air for the first few days and the temp. should not exceed 40° CO₂ should not enter the chamber until large amts. of basic Pb acetate have been formed and as the temp. subsequently rises to a max. of 75 or 80°, the concn. of the AcOH used should be gradually reduced to a max. of 0.6% at the end of the process. Antiquated washing, drying and grinding methods should be discontinued. F. A. WERTZ

The permanency to light of pigments, and its determination in natural and artificial light sources. H. WAGNER. *Farben-Ztg.* 30, 2991(1925).—The quartz-Hg vapor lamp gives the same final bleaching effect as sunlight in $1/5-1/30$ of the time. The type and quantity of vehicle used in the test influence the results. F. A. WERTZ

The evaluation of white pigments. P. WOLSKI. *Farben-Ztg.* 30, 2993(1925).—The brightness of a dry white pigment is detd. by direct comparison with a standard series representing 100 to 90% abs brightness. An index of the hiding power in oil is the amt. of lampblack necessary to reduce the brightness to 50% of the original brightness as detd. by measurements with a shadow photometer. The measure of the spreading rate in oil is the area which when painted with 1 kg. of pigment on a black undercoat will show a brightness of 50% of the original brightness. F. A. WERTZ

Test methods for rust-preventive paints. CARL BINGGELY. *Schweiz. Chem.-Ztg.* No. 13, 121-3(1925).—A polished steel plate is given 2 coats of the test paint which is allowed to dry 8 to 10 days. The panel is then exposed to steam for 10 to 12 hrs., dried at 100° for 1 hr., and a portion of the film removed with CS₂. No corrosion of the steel should have occurred. Another test method consists of placing 5% H₂SO₄ on 2 air-dried coats of paint over iron, allowing it to remain 24 to 48 hrs. and noting whether the paint blisters. These are the 2 most generally used tests, but they measure impermeability of the film and resistance to acid rather than rust-inhibitive properties. A convenient method for detg. the permeability is to have the Fe panel serve as one electrode, and a N-KCl soln. on the paint film as the other, and measuring the p. d. between them. Illus. (See C. A. 19, 3025.) F. A. WERTZ

A method for making paint and varnish films for testing. D. DAVIDSON. *Paint, Oil, and Chem. Rev.* 80, No. 11, 10(1925).—A measured vol. of varnish is placed on the center of a plate glass disk, and another similar disk is pressed down on it until the varnish covers the whole of the adjacent surfaces. The disks held in a vertical position are then slid apart, and the thickness of the film on each is calcd. If the films are to be stripped, one of the disks may consist of amalgamated brass, or may be covered with glue-sized paper. F. A. WERTZ

The determination of water in paints. T. H. BOWLES, T. H. ADAMS, C. A. KLEIN, AND J. A. F. WILKINSON. *J. Oil and Colour Chemists' Assoc.* 8, 206-8(1925).—For the detn. of H₂O in paints according to the specification of the British Eng. Standards Assoc., mix 100 g. of the sample in a flask with 100 cc. petroleum spirit, b. 80-100°, and 1 cc. of dry Am or Et acetate. Then attach the flask to the side arm of a special distillate receiver having a narrow graduated tube at the bottom into which the H₂O collects on distn., while the petroleum spirit returns through the side arm to the flask. Cf. C. A. 19, 2277, 2465. F. A. WERTZ

A new color standard for varnishes. S. C. ATKINSON AND B. C. JAMES. *J. Oil and Colour Chemists' Assoc.* 8, 208-9(1925).—The disadvantages of solns. of K₂Cr₂O₇ in concd. H₂SO₄, of caramel in H₂O, and of other solns. at present used for varnish color standards are discussed. A satisfactory standard is obtained by using a mixt. of 20 g. NiSO₄·7H₂O in 100 cc. H₂O, and 1.25 g. of I in 100 cc. H₂O. The amt. of KI present does not affect the final color. A definite vol. of the I soln. is measured into a beaker and the NiSO₄ soln. added until approx. the same shade as that of the varnish under examn. is obtained. The correct depth of color is then adjusted by the addn. of a measured quantity of H₂O. Comparison is made by viewing an equal vol. of the varnish and the soln., in tubes 1.1 cm. diam. Close matches are possible, and sealed tubes over 3 months old show no alteration in color. F. A. WERTZ

The examination of boiled linseed oil for rosin. HANS WOLFF. *Farben-Ztg.* 30, 2795-6(1925).—The Lieberman-Storch test for rosin in raw and boiled linseed oil is reliable only when the result is negative, but a positive color reaction is not an infallible indication of the presence of rosin. Jensen (Holde, *Die Kohlenwasserstofföle und Fette*, p. 605 (1924)) states that the Lieberman color reaction is more intense, the greater the amt. of unsapon. matter in the oil. Examn. of 78 raw oils showed that approx. half of those contg. more than 1.5% unsapon. matter gave positive reactions. The fatty acids of these oils, after sepn. of the unsapon. matter, gave a negative reaction

in nearly every case. When the raw oils were heated with driers, the resultant boiled oils showed an even higher percentage of positive reactions, especially in those containing Mn. The test for rosin is best carried out on the fatty acids; if the color reaction is positive, rosin is indicated only through formation of NH_4 abietate with its characteristic crystal form, and gel formation in benzene. A convenient procedure for making the test is given and results are tabulated.

F. A. WERTZ

The abrasion resistance of varnishes. W. C. ARSEM. Paint Manufs. Assoc. of U. S., *Circ.* No. 244, 45-50(1925).—The "abrasimeter" for measuring the abrasion resistance of varnish films, in its simplest form, consists of a steel ball bearing, three-sixteenth inch in diam. mounted at the end of a pointed wooden rod fastened to the right-hand pan of a trip scale. The wt. on the scale pan required to produce a scratch on a varnish film moved about under the ball is a measure of the abrasion resistance. The critical point on films of uniform thickness and degree of dryness can be detd. to within 5 to 10%. With this device it is possible to follow the progress of drying and hardening of a varnish, to compare different varnishes, and to show the effect of varying proportions and treatments. It is to be expected that the greater the continuity of the gel structure, resulting from the drying oil in the film, the greater the abrasion resistance. Results on several varnishes and lacquers are plotted. A great increase in abrasion resistance results when more than 75% of gel-forming substance is present, probably because of the proximity and particular arrangement of the mol. units of the gel.

F. A. WERTZ

Sediments in varnishes. FELIX WILBORN. *Farben-Ztg.* 30, 2862-3(1925).—Sediment in varnishes generally consists of insol. Pb or Mn salts of palmitic, stearic, or oxy fatty or resin acids; this is in accord with earlier reports (*C. A.* 16, 349). Investigation of complaints on unduly turbid varnishes during the winter traced the cause to the low temp. especially in combination with traces of moisture retained in the previously steamed-out barrels.

F. A. WERTZ

The production of oil varnishes with sulfur chloride. HANS BRENDL. *Farben-Ztg.* 30, 2734-5(1925).—The treatment of drying oils with SCl_2 to produce special varnishes is difficult to carry out, and the resultant products have no particular merits. Instead of being good rust-preventive coatings as often claimed, such varnishes may be corrosive because of the residual HCl which they contain.

F. A. WERTZ

The chemistry of drying oils. II. G. W. ELLIS. *Chemistry & Industry* 44, 463-ST(1925); cf. *C. A.* 19, 3380.—Linseed oil, oxidized to different degrees, was extd. with petroleum ether, and the insol. portion then dissolved in CCl_4 -alc. mixt., and fractionally pptd. with petroleum ether or with dil. alc. Ultimate analyses, acid and sapon. nos. of the products are tabulated; these indicate that hydrolysis of the oxidation product, due to the effect of the solvents employed, had taken place, and suggest the existence of isomeric forms of the same oxidized products. The process involving the soln. of linoxyn is the one liable to cause hydrolysis; when thoroughly dried solvents are used, the resultant purified linoxyn, representing 72.5% of the original oil film, shows an ultimate analysis which agrees well with the ascribed formula $\text{C}_{37}\text{H}_{50}\text{O}_{20}$. The acid no. of the purified linoxyn indicates monobasic acidity; I no. 12.1. Linoxyn in soln. readily reduces Fehling soln. and AgOH , and gives a blue coloration with KI-starch soln. acidified with AcOH .

F. A. WERTZ

Pyroxylin invades the varnish plant. ANON. *Chem. Met. Eng.* 32, 747-9(1925).—A description of the plant equipment, and the method of manufg. lacquers at the Beck-with-Chandler plant.

F. A. WERTZ

The stability of nitrocellulose. J. B. WIESEL. *Paint, Oil and Chem. Rev.* 80, No. 10, 8, 20, 21(1925).—A popular account of the rapidly growing field of nitrocellulose coatings, with particular reference to the importance of stability as regards permanence of the coating.

E. M. SYMMES

Bulking value of nitrated cotton in lacquers. Spreading rate of colored crushing lacquers and oil paints. Temperature of gasoline in painted tanks. H. A. GARDNER. Paint Manufs. Assoc. of U. S., *Circ.* No. 247, 59-61(1925).—One lb., dry basis, of nitrated cotton of any viscosity, when dissolved in lacquer solvents, "bulks" approx. 0.1 gal. Lacquers have a much lower spreading rate than oil paints. Results of comparative small panel tests are tabulated. Additional tests on the comparative temps. of gasoline tanks painted with white or with Al paint, made with small containers in the lab., indicate that white paint is more efficient in keeping the temp. low. Results are tabulated.

F. A. WERTZ

Tetralin, dekalin, hexalin as solvents and thinners. H. A. GARDNER. Paint Manufs. Assoc. of U. S., *Circ.* No. 248, 62-74(1925).—Hexalin is the only one of these

solvents that has any pronounced action on nitrocellulose. Abstracts from the literature on the products are appended. F. A. WERTZ

Nitrocellulose varnishes and varnish paints. Applications in the automobile and wood working industries. J. H. FRYDLANDER. *Rev. prod. chim.* **28**, 577-84(1925).—A review of recent progress in their manuf. and application. A. P.-C.

Colors for lacquers. A. F. BROWN. *Paint, Oil and Chem. Rev.* **80**, No. 10, 12, 21 (1925).—A review. In general the color found satisfactory for use in oleoresinous varnishes will be found adaptable to the manuf. of pigmented lacquers although some org. lakes and toners that are non-bleeding in oil varnishes will bleed in lacquers. F. A. W.

Tricresylphosphate as a lacquer plasticizer. M. R. TRIMMER. *Paint, Oil and Chem. Rev.* **80**, No. 10, 10(1925).—Tricresylphosphate is odorless, colorless, neutral, non-volatile, and non-inflammable; $d_{15} 1.176$. It is slightly less viscous than glycerol and is miscible in all proportions with the common org. solvents. When added to lacquers it imparts toughness, flexibility, gloss and flowing properties. On heating at 45° for 50 days, practically no evapn. takes place. Pigmented lacquers can conveniently be made by grinding the pigments in tricresylphosphate, and then stirring the paste into the clear lacquers. F. A. WERTZ

Aviation dopes or varnishes. MAURICE DESCHIENS. *Chemistry & Industry* **44**, 902-7(1925).—A review of the history of airplane dopes, of the manuf. of cellulose acetate, the methods of dissolving it in solvents, application of the dope to the wing fabric, etc., with typical formulas. F. A. WERTZ

Physiological effects of vapors from a few solvents used in paints, varnishes and lacquers. H. A. GARDNER. *Paint Manufs. Assoc. of U. S., Circ. No. 250*, 89-149 (1925).—Tests were made on rabbits of the effect of the vapors of 6 grades of turpentine, including pure gum spirits and a number of grades of wood turpentine of various degrees of refinement, of mineral spirits, C_6H_6 , solvent naphtha, butanol, furfural and dipentene. Blood charts, clinical reports, autopsy and pathol. reports are given in detail. C_6H_6 is the only one of these solvents which has a marked deleterious effect upon the animals, producing definite symptoms of poisoning and death. The higher homologs of C_6H_6 appear to be much less poisonous, and solvent naphtha, 160° , showed no deleterious effects except slight mucuous membrane irritation. Vapors of mineral spirits, gum spirits turpentine, or highly refined steam-distd. wood turpentine are non-toxic. The vapors of lacquers contg. Am acetate, Bu acetate, toluene, alc., or furfural are not dangerous where ordinary ventilation exists. F. A. WERTZ

Old and new about colophony. A. SAMTLEBEN. *Farben-Ztg.* **30**, 2863-5(1925).—A brief review is given of the variously ascribed constitutional formulas for abietic acid. Since rosin appears to belong to a terpene group, and the fossil resins may have originally consisted of closely related substances that have been transformed by time, attempts were made to bring about the polymerization of rosin and its glycerol ester by long heating, with and without the use of catalysts and pressure. Most of these attempts gave no results, but a certain org. acid catalyst produced a product resistant to acids and alkalis, m. 84° , that produced an excellent varnish. S. believes that research in this direction might lead to a method for the "copolisation" of rosin. F. A. W.

Properties of Malayan damars. T. H. BARRY. *J. Oil and Colour Chemists' Assoc.* **8**, 125-6, 204-6(1925).—A general description of the origin and nature of various varieties of Malayan damars is given, and their m. p., acid no., insol. matter in $CHCl_3$, and ash are tabulated. Cf. *C. A.* **19**, 408. F. A. WERTZ

Lead resinate solutions. I. CH. COFFIGNIER. *Bull. soc. chim.* **37**, 1078-85 (1925); cf. Nicolardot and C., *C. A.* **14**, 1449.—Solns. were prepd. contg. 5-25% of Pb resinate (contg. 5 and 10% PbO) in C_6H_6 , spirits of turpentine and white spirit (d 0.780). Periodical detns. were made of the viscosity, ppt. and ash in the ppt. The results (given in detail) show that the resinate contg. 5% PbO gives C_6H_6 solns. which are stable for at least 2 months, spirits of turpentine solns. in which the pptn. is slight while the increase in viscosity with time is greater the stronger the soln., and white spirit solns. from which the resin ppts. out at an irregular rate even after 6 months. The resinate contg. 10% PbO behaves in a very similar manner, but the ppts. from the C_6H_6 and white spirit solns. were greater than those with the 5% PbO resinate. The spirit of turpentine solns. give practically no ppt. in 2 months, but the increase in viscosity is considerably higher than that with the 5% PbO resinate, and there is appreciable swelling of the granules in the 25% soln. The pptn. of resins is attributed to a reaction represented by $2(RCO_2)_2Pb - RCO_2H \longrightarrow (RCO_2)_2Pb(m - n)RCO_2H +$ pptd. resins sol. resins

A. PAPINEAU-COUTURE

Some problems of the paint and rubber industries (PORRITT) 30. Anaconda electrolytic white lead (BOWMAN) 4. Reducing the viscosity of nitrocellulose solutions for use as a varnish or lacquer] (U. S. pat. 1,553,494) 23. C pigment (U. S. pat. 1,552,473) 23.

"Copper paint." R. G. GIANELLI. U. S. 1,555,198, Sept. 29. A solid compn. adapted for liquefaction by heating for coating hulls of ships, etc. comprises tallow 8, powd. C 2, powd. "bluestone" 2 and Pb_2O_4 2 parts.

Water-paints. F. SCHWARTZ and E. GIL-CAMPORRO. Brit. 231,457, March 26, 1924. A H_2O -paint or varnish is obtained by saponifying gums or resins in the presence of NH_4 resinat and mixing the soap obtained with an oil saponified with NH_4 and an aq. soln. of casein, albumin, ceratin or similar substance.

Paint or printer's ink solvent. J. E. RHODES. U. S. 1,553,914, Sept. 15. A mixt. of kerosene 28 satd. with rosin, varnish 1 and a double silicate of Mg and Ni 1 part is used for thinning printer's ink, etc.

Bituminous paints. P. LECHLER. Brit. 231,411, April 25, 1924. Coal-tar pitch, chlorobenzene and C_2H_5Cl may be used with raw cresols and naphtha, with addn. of soaps of Cu or Hg (which may be formed in the paint mixt.) if anti-fouling paints are desired.

Carbon pigment. D. J. OGILVY. U. S. 1,550,042, Aug. 18. A carbonaceous flame (which may be produced by the combustion of gas, oil, pitch or resin) is impinged against a wet surface of a revolving cylinder.

Pigments. L. A. SANDERS and K. A. ROTH. Brit. 230,883, Nov. 9, 1923. Pigments (or colored powders which are converted into pigments by calcination) are produced by pptg. inorg. colored substances from an aq. soln. upon a large excess of a finely divided inorg. carrier such as chalk, cement; ground shells, soapstone, gypsum, infusorial earth, trass, kaolin, marl, feldspar, hornblende, asbestos, loam, fluorspar, lime, waste marble, pumice, mica or dolomite. Org. substances such as alizarin may be added as may also $Al(OH)_3$ or casein.

Basic lead sulfate pigment. J. A. SCHAEFFER, J. H. CALBECK and B. S. WHITE. U. S. 1,555,520, Sept. 29. Pb ores and similar materials contg. S are treated in low cupola furnaces for the production of a basic Pb sulfate fume, and gas and fume thus formed are drawn through a system of hot flues and cooling devices. Atomized Pb is simultaneously sprayed into a heated furnace chamber contg. O and SO_2 to produce a basic Pb sulfate fume. The fumes and gases from the 2 furnaces are mixed and the fume is sepd. by screening. Cf. C. A. 19, 1060.

Paint-removing composition. W. J. TENNIS. U. S. 1,553,485, Sept. 15. Denatured alc. 2 qts., C_2H_5 3.75 pints, H_2SO_4 $1/4$ pint, paraffin $1/4$ oz. and soap 3 oz.

Sympathetic ink. A. ROGERS. U. S. 1,553,556, Sept. 15. See Can. 246,943 (C. A. 19, 1353).

Doped airplane fabric. A. F. SULZER. U. S. 1,552,808, Sept. 8. Airplane fabric is doped and rendered taut with a coating contg. H_2O -insol. ethyl cellulose which is highly resistant to becoming brittle at low temps. A layer applied directly to the fabric contains substantially no plastifiers and successive layers applied over it contain plastifiers such as triphenyl phosphate and camphor.

Varnish-removing composition. A. SHETZLEY. U. S. 1,553,724, Sept. 15. Na percarbonate 98, and Na peroxide $1 1/2$ parts are dissolved in boiling H_2O .

Synthetic resins. A. DANILOWITSCH and G. PETROFF. Brit. 231,501, March 25, 1924. In the condensation of phenol with formaldehyde or formaldehyde-producing substances, naphthalene- α -sulfonic acid is used as a catalyst, with glycerol and fusel oil to retard hardening, the product is dehydrated *in vacuo* and then hardened by heating it in molds to obtain a transparent infusible product.

Resinous phenol-aldehyde condensation products. CANADIAN ELECTRO PRODUCTS CO., LTD. Brit. 232,277, Oct. 18, 1923. $PhOH$, cresol or naphthol is caused to react with C_6H_5 in the presence of H_2SO_4 and Hg sulfate or other catalyst and the product is further treated with an aldehyde, e. g., AcH , CH_2O or its polymers or furfuraldehyde. Amino compds. or paraformaldehyde may be used as hardening agents.

Rosin composition. H. S. MILLS. U. S. 1,556,237, Oct. 6. A mixt. adapted for rosinning violin bows is formed by blending rosin with gum sandarac in a volatile solvent such as alc., using sufficient rosin to constitute at least 80% of the product.

Lac. T. W. BARBER. Brit. 231,621, Feb. 8, 1924. White or bleached lac is pressed into thin sheets, strips or threads to eliminate its content of acidulated H_2O and produce a readily sol. product which does not easily deteriorate.

Lithopone. FARBENFABRIKEN VORM. F. BAYER & Co. Brit. 225,523, Nov. 30,

1923. To render lithopone fast to light, it is associated with 0.02–0.5% of heavy metal compds. such as those of Fe, Co, Ni and Cu.

Vertical tubular retort for lithopone treatment in muffle furnaces. W. R. MACKLIND, G. C. MCCARTEN, W. S. STEVENS, E. C. HOLTON and H. J. HAIN. U. S. 1,550,271, Aug. 18.

Coating wood, metal, leather, etc., with "Zellon." R. OCHSCHIM. Brit. 231,129, March 22, 1924. Heat, pressure and a cementing soln. of "zellon" (a non-inflammable celluloid-like material) are used to unite "zellon" sheets to other materials.

Compositions for making printers' blankets. A. F. DECKER. Brit. 231,964, Jan. 22, 1924. A layer of rubber or cork compn. is covered with fabric facings at least one of which is wool. Formulas are given of cork and rubber mixts. and of nitrocellulose compns. suitable for use as ink-repellent coating material. Cf. C. A. 19, 2138.

Printing surfaces. E. FABIAN. U. S. 1,549,859, Aug. 18. A metal foundation such as an Al or silvered Cu plate is treated with HCl, HNO₃ or other acid reagent capable of transforming the surface portion of the plate into a metallic salt, an original design is applied with an ink contg. NH₃ or other alk. pptg. agent, to ppt. another metal compd. from the metal salt on the plate. The foundation is then inked for printing, with an ink having a fatty base. U. S. 1,549,860 specifies treating foundation plates with an acid soln. of a metal salt which may contain Al(NO₃)₃ and chlorides of Mg and Fe.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Fat cleavage by means of zinc and the purification of the resulting glycerol. J. KRAUSE. *Z. deut. Oel-Fett-Ind.* 45, 527–9(1925).—Fat cleavage by means of ZnO yields fatty acids of good color; inferior grades of fat yield acids the color of the original fat, but are lighter if metallic Zn powder is used simultaneously with ZnO. To obtain high % of cleavage it is essential to work with purified oils, avoid permanent emulsions, use clean ZnO and pure H₂O; chem. softened H₂O often contains free alkali which forms soaps in the autoclave. The glycerol liquor is purified with milk of lime, filtered, acidified with H₂SO₄, neutralized with Ca(OH)₂ and again filtered. P. ESCHER

The hardening of fats. V. SCHWARZKOPF. *Z. kompr. u. flüssige Gase* 24, 32–5 (1925).—Brief review of the technical features of this industry. R. L. DODGE

The determination of moisture in fats and oils. W. NORMANN. *Z. angew. Chem.* 38, 592–3(1925); cf. C. A. 19, 2277.—A discussion of the methods of other workers. E. SCHERUBEL

Pressing or extracting. K. LÖFFL. *Seifensieder Ztg.* 52, 733–4(1925).—Decision whether pressing or extg. is desirable must be made for each oil separately. Table oils with a specific aroma or flavor require cold pressing. Oils that are to be worked up into edible fats, and the various technical oils call for extn., for economic reasons. It is essential to remove all traces of the solvent from the residual press cakes if used as animal fodder. P. ESCHER

Extraction of the highly unsaturated fatty acids from fish oils. YOSHIYUKI TOYAMA and TOMOTARO TSUCHIYA. *Chem. Umschau Fette, Oele, Wachse u. Harze* 32, 204–7(1925).—In order to isolate the most highly unsatd. acids from fish oils T. and T. employed 3 methods: (1) The method based on the insolubility of Na soaps in acetone contg. H₂O. (2) In acetone contg. alc. (3) In acetone contg. H₂O and alc. The 1 no. of the isolated acids in all cases is higher the less H₂O or alc. is present in the acetone. T. and T. recommend method 3 as the most useful, because the sepd. acids have less tendency to form a sticky mass difficult to break up. All 3 methods are only qual. seps., but it is possible to obtain by their means concd. portions of highly unsatd. fatty acids. The constns. of the fatty acids of the original oils are given in 3 tables. P. ESCHER

The constitution of tetradecylenic acid from sperm oil. MITSUMARU TSUJIMOTO. *Chem. Umschau Fette, Oele, Wachse u. Harze* 32, 202–4(1925).—The preliminary formula CH₃(CH₂)₇CH:CH(CH₂)₅COOH which T. gave for tetradecylenic acid (C. A. 17, 3618) is confirmed through the isolation of glutaric acid from the products of oxidation by Harries' ozone method. The acid was obtained from the lower fatty acids of sperm oil by means of the Pb salt-petroleum ether method, and was treated in cooled CHCl₃ soln. with O₃, contg. 9–12% O₃, yielding the ozonide peroxide, C₁₄H₂₆O₆, d₁₅ 1.063 and n_D₂₀ 1.4645. This peroxide was decompd. by hot H₂O, the oily top layer extd. with ether, the ether soln. shaken with NaHCO₃ and the resulting products were purified and

analyzed. From the ether soln. were isolated nonyl aldehyde and pelargonic acid (4.7 g.) and from the bicarbonate product as well as from the H_2O soln. were isolated glutaric acid and the half aldehyde of glutaric acid (?) (4.0 g.), a total yield of 8.7 g. from 15 g. ozonide peroxide, small but sufficient to fix the position of the double C bond in tetra-cyclyenic acid.

P. ESCHER

Constituents of the marking nut: *Semecarpus anacardium* Linn. D. SATYANARAYANA NAIDU. *J. Indian Inst. Sci.* **8A**, 129-41(1925).—Examn. of the products obtained by successive extrn. with light petroleum, alc. and H_2O resulted in the isolation of a fixed oil from the kernels, catechol (0.1% on the wt. of the nuts), *anacardol*, $C_{18}H_{30}O$ (new), an acid $C_{17}H_{16}O_6$ yielding an insol. Ba salt, an acid $C_{18}H_{14}O_6$ yielding a sol. Ba salt, and the K salt of an acid with strong reducing properties which has not yet been isolated. The fixed oil from the kernels resembles cashew-kernel oil and had d_{15}^{25} 0.9277, n_D^{60} 1.4574, acid value 23.9, sapon. value 216.5, I value 101.4; and the fatty acids of the oil had Hehner value 87.5, n_D^{60} 1.4473, titer test 12.2, mean mol. wt. 293, satd. acids 13.3%, m. p. of satd. acids 51.1–51.5°, unsaponifiable 0.82% (of which 30% is a sterol). *Anacardol* is a mobile, pale yellow oil when freshly distd., turning brown and then black on exposure to the atm., with strong corrosive action on the skin, d_{15}^{25} 0.9693, n_D^{25} 1.5078, C 82.7%, H 11.3%, O 6.0%, mol. wt. (via Fawsitt, *C. A.* **14**, 242) 275, OH (via Hibbert and Sudborough, *J. Chem. Soc.* **85**, 933(1904)) 6.26. Br in CCl_4 soln. substitutes for 3 H atoms, but forms no additive compd. The oil is sol. in all org. solvents, including petr. ether, insol. in H_2O , NH_3 and Na_2CO_3 , and sol. in KOH and NaOH solns. with darkening; the alc. soln. darkens rapidly, with $FeCl_3$ gives a dark green coloration and finally a dark colored ppt., gives ppts. with salts of Ba, Al, Pb, and Zn all of which tend to turn dark-green and liberate dark oily products when acidified; the soln. in anhyd. Et_2O or C_7H_8 evolves H in the presence of Na. Acetylation gives a mobile non-corrosive oil, n_D^{26} 1.4875. Benzoylation in C_6H_5N soln. gives a yellow, viscous Bz deriv., which on keeping deposits BzOH. No definite compds. could be isolated from the products of oxidation with Br, HNO_3 - H_2SO_4 , CrO_3 or $KMnO_4$. Distn. with Zn dust and subsequent rectification at 12 mm. gave an oil b. 110–20° (mainly 115°) at 12 mm., n_D^{28} 1.4918, C 87.7%, H 10.75%. White *anacardol* picrate, m. 100–1°, was prepd. The acid $C_{17}H_{16}O_6$ dissolves in alkalis to a yellowish or orange-red and is repptd. by passing CO_2 ; in alc. soln. it gives a violet coloration with $FeCl_3$; in NH_3 soln. it reduces $AgNO_3$ when gently warmed and is readily attacked by $KMnO_4$; it forms insol. Ca, Ba, Cu, Pb and Ag salts (the Ag salt readily decomposes); on being fused with phthalic anhydride and made alk. it gives a carmine-red phthalcin deriv.; it couples with $PhNH_2$ or sulfanilic acid; and possesses most of the characteristics of a phenolic acid. With Ac_2O and $AcONa$ it gives an almost colorless powder, m. 126–7°, corresponding with none of the Ac derivs. of the acid; with $BzCl$ and alkali it gives colorless crystals, m. 142–3°; nitration gives a product m. 110–2°; bromination gives $C_{17}H_{11}Br_6O_6$, m. 160–1°; with Me_2SO_4 in presence of 40% KOH it gives a neutral substance (probably an ether-ester) m. 120–1° and an acid (probably an ether-acid) m. 161–3°. The ordinary reagents of the ketone group did not give definite products. The soly. and reactions of the acid $C_{18}H_{14}O_6$ are very similar. In alc. soln. it gives a reddish brown coloration with $FeCl_3$.

A. PAPINEAU-COUTURE

Argemone oil. S. N. IYER, J. J. SUDBOROUGH AND P. R. AYYAR. *J. Indian Inst. Sci.* **8A**, 29–38(1925).—Extn. of the crushed seed of *Argemone mexicana* L., with petr. ether gave 29.4% of a yellow oil with d_{20} 0.9209, n_D^{60} 1.4601, sapon. no. 190, I no. 121, Ac no. 39, acid value 12.0, Reichert-Meissl no. 0.3, Polenske no. 0.2, unsaponifiable matter 1.3%, Hehner no. 93.0. The curve showing the relation between n and I nos. of hydrogenated samples of oil is characteristic and resembles that for the rape oils. This is due not to the presence of acids of high mol. wt. such as behenic, lignoceric, or erucic, but to a certain quantity of hydroxy acids. The values given show that more than one-third of the total OH is present in the unsatd. acyl groups and the remainder in the alkyl group, presumably as diglyceride, and that the acyl OH undergoes complete reduction and the alkyl OH partial reduction during hydrogenation. The mixed acids consist of palmitic 7.95, stearic 5.95, palmitoleic 5.87, oleic 21.79, linolic 48.02, linolenic 0.58, ricinoleic 9.84%. The unsapon. contained 35% *sitosterol*.

Deodorization of fish oil and fish-oil soap. F. R. TAPPERT. *Z. deut. Oel-Fett-Ind.* **45**, 446–8(1925); illus.—The app. and process for deodorizing fish oils and fish-oil soaps are described: the oil is heated to 280–300° for 2–3 hrs. under a slight vacuum and later is treated at 50–60° with $1/2$ –1% of 66° H_2SO_4 to remove albuminous and mucilaginous matter. The fish-oil soap is deodorized at the same temp. but under a pressure of 40 atm.

P. ESCHER

Idrapidspalter. M. GELBKE. *Chem. Umschau* **32**, 213-20(1925); cf. *C. A.* **19**, 2753, 3028 and following abstr.—Analysis of an Idrapidspalter showed 81.6% effective sulfonic acid, 5.8% unsapon., 1.9% free H_2SO_4 and 10.6% H_2O . The concd. product varied between 10 and 15% ether-insol., 85-90% ether-sol., 5-10% H_2O , 2-7% H_2SO_4 , 6-11% unsapon. (aromatic hydrocarbons) and 75-80% fat-splitting aromatic sulfonic acids. These sulfonic acids can be sepd. into 20-25% cryst. aromatic acids and 60% high mol. polymerized, liquid, red-brown sulfonic acids of unknown constitution, but highly active, the true cleavage agents. Comparative expts. for splitting effects of other Twitchell reagents lead G. to the following conclusions: Idrapidspalter, when freed from its accompanying free H_2SO_4 , possesses an activity which is ineffective for industrial use; the satisfactory effectiveness of Idrapidspalter resides in its free H_2SO_4 , introduced during manuf. Its activity is below that of the "Kontakt-spalter" under like conditions. Treatment of the Idrapidspalter with ether does not cause any mol rearrangement but simply removes some 20% ballast which contains no sulfonic acids.

P. ESCHER

Idrapidspalter. SCHRAUTH. *Z. deut. Oel-Fett-Ind.* **45**, 493-4(1925).—An answer to Gelbke's article (*C. A.* **19**, 2753) in which he claims that Schrauth's Idrapidspalter is less active than the standard product. Cf. preceding abstr.

P. ESCHER

• **Emulsifying power of various soaps.** J. AUGUSTIN. *Seifensieder Ztg.* **52**, 731-2 (1925).—A brief review of the principles of forming emulsions by means of soaps, principally Na and K soaps.

P. ESCHER

Splitting fats in autoclave practice. C. SCHULZ. *Chem. Umschau* **32**, 186-8 (1925).—An account of obtaining 93-98% splitting effects by dividing the process into a preliminary autoclaving of 4 hrs. to an 80-85% split and 2nd final split of 3 hrs. using an acid treatment and a wash between the 2 operations.

P. ESCHER

Catalysts for saponification of fats and their special uses. A. BEYER. *Trib.* **3**, 903-9(1925).—Brief review of the manuf. and use of Twitchell's reagent, Paal's "Pfeilringspalter" and Petroff's "T contact."

A. PAPINEAU-COUTURE

Stratification in settled soaps. W. HEIM. *Z. deut. Oel-Fett-Ind.* **45**, 429-30 (1925).—A tendency exists for settled soaps in their top layer to be richer in fatty acids by as much as 4.18% than the lower layer, due to a lower H_2O content; foreign salts are slightly higher toward the bottom layers.

P. ESCHER

A new method for the manufacture of cheap transparent soap. H. KASARNOWSKI. *Z. deut. Oel-Fett-Ind.* **45**, 445-6(1925).—K. adds to settled or cold-made soaps 30 to 50% of "diaphan-oil," a mixt. of methylhexalin and Na oleate, obtaining a transparent soap which after several days is of good consistency. This method is also applicable to laundry soaps. Cf. *C. A.* **19**, 2421.

P. ESCHER

Modern manufacture of candles and wax-goods. A. LÖDL. *Seifensieder Ztg.* **52**, 544-7, 567-70, 589-90, 606, 624-5(1925); illust.—A general review under the following captions. I. Candles; raw materials. II. Beeswax bleaching. III. Technical wax goods.

P. ESCHER

Protective action of soaps (BHATNAGAR, *et al.*) 2. Soaps and the theory of colloids (MCBAIN) 2. Stationary extraction plants (HASSEL) 13. Converting oils (Brit. pat. 231,157) 22. Distilling fatty acids (Brit. pat. 231,686) 13. Apparatus for separating water and impurities from soaps, fats, etc. (U. S. pat. 1,555,231) 4.

Thickening fatty oils. W. CALDERWOOD, A. E. WEBB and C. A. REIHL. Brit. 217,150, Dec. 31, 1923 and U. S. 1,514,432, Nov. 4, 1924. Oils are thickened without oxidation by heating and cooling in a filled hermetically sealed vessel connected through a sealing trap with supply and expansion vessels.

Purifying fats and oils. H. BOLLMANN. Brit. 231,126, March 24, 1924. Fats and oils are decolorized by mixing with Al silicate or other decolorizing powder and passing the mixt. through a tube provided with agitators and then immediately through a centrifuge to sep. the powder.

Refining cotton oils. D. MCNICOLL. Brit. 232,361, Feb. 6, 1924. Cotton oils and the fatty acids obtained as by-products in refining the oils are decolorized by treatment with Na decaborate and NaCl or with other prepn. in aq. soln. of a metal borate which is acid to phenolphthalein in aq. soln. The purified oils may be further refined with NaOH. The coloring substance obtained, gossypol, may be used as a substitute for logwood, cutch, fustic, etc.

Purifying fats and fatty oils. H. BOLLMANN. Brit. 231,791, Sept. 3, 1924. Oils or fats are repeatedly atomized with superheated steam as they are passed downwardly through a column still connected with a vacuum pump for withdrawal of vapors.

Extracting fatty oils from seeds, etc. G. KAMMERMANN. Brit. 231,296, Feb. 22, 1924. Expression of oil from seeds, etc., is facilitated by a preliminary vacuum treatment followed by addn. of moisture at least to replace that removed. Cf. C. A. 18, 338.

Olive oil. S. HILLER. U. S. 1,553,162, Sept. 8. The constituents of olive meats are reduced to a state of colloidal suspension in an emulsion of the oil and H_2O which they contain, and the suspended solids, oil and H_2O are then sepd. from each other, c. g., by centrifuging.

Soap powders containing oxygen. R. KORSALT. U. S. 1,555,588, Sept. 29. Finely pulverized $KMnO_4$ is mixed with paste-like neutral soap, calcined Na_2CO_3 is added to form a dry granular product and this is mixed with a perborate.

28—SUGAR, STARCH AND GUMS

F. W. ZERBAN

The use of Norit in Czechoslovakian sugar factories. BERTHOLD BLOCK. *Centr. Zuckerind.* 33, 781-3, 818-21 (1925).—Detailed flow sheets of the use of Norit in the refinery at Ratbor, in refining at Klittenberg, and in working beets at the latter factory. Too detailed to abstract

W. L. BADGER

The origin of the Dutch sugar standards. W. M. F. MANSVELT. *Planter and Sugar Mfr.* 75, 148-9 (1925).—The Netherlands Trading Soc. in 1839 found a broker submitting samples which were not representative of the lot. To avoid the recurrence of this, a set of samples grading from the very darkest to white sugar was made up. The original no. of 21 was later reduced to 18. These have been revised as the quality of the sugar produced has been improved till they now number from 8 to 25. Their use has permitted closer grading. Samples are now issued by the Society annually and in many countries still serve as the basis of classification. Polarization is the U. S. basis of evaluation but the color classification is also considered. C. H. CHRISTMAN

Indicators in the sugar laboratory. H. A. COOK. *Sugar* 27, 117-8, 172-4 (1925); cf. C. A. 19, 2755.—Lack of definiteness in the expression of acidity and alk. in the sugar labs. has been prominent. Studies in clarification and the keeping qualities of juice have shown the importance of considering the degree of acidity, or p_H , rather than total acidity or alk. as formerly expressed. With inversion in clarified juices occurring at more alk. p_H ranges not formerly appreciated, a definite expression of acidity is necessary to locate this danger zone. The use of litmus is not recommended because of its broad p_H range and lack of sensitiveness. The indicators suggested by Clark are suitable for sugar work. The spot test method for detg. p_H is used. A color chart on celluloid is being prepd. for factory control. C. H. CHRISTMAN

Color comparator for hydrogen-ion concentration. G. P. MEADE and R. BAUS. *Planter and Sugar Mfr.* 74, 509 (1925).—A sliding tube rack encased in a thin metal cover is fitted with permanent colorimetric standards, the tubes being alternated with tubes of distd. H_2O . In front of the sliding rack and before suitable apertures in the cover are sockets for removable tubes. A ground-glass back is located on the opposite side. For refinery liquors, bromothymol blue is used. Five cc. liquor is dild. with 15 cc. water and 10 cc. transferred to each of the tubes, 0.5 cc. indicator added to one tube and the comparison made with the standards. C. H. CHRISTMAN

Influence of changes in alkalinity on changes in color of sugar solutions. HARALD LUNDÉN. *Centr. Zuckerind.* 33, 1013 (1925).—Changing the p_H of a soln. of molasses or 2nd raw sugar from 10 to 1 caused a lowering of color by 13-18% of the color at $p_H = 10$. A sugar prepd. from affination liquor has its color decreased 60% by the same change. Cane products are more sensitive; if the color of affined sugar at $p_H = 10$ is 1.00, at $p_H = 2.0$ it is only 0.14. After-products show a little less change. The curves of color vs. p_H show a point of inflection like an electrometric titration. It is assumed that there are 2 colored substances present—one, an "old" substance present mainly in after-products, not sensible to p_H ; the other, the "new" color, possibly formed by the action of alkali on sucrose, is an indicator. Its neutral point is $p_H = 5.10$ for beet products and 7.0 for cane, hence it is possible that beet and cane sugars owe their colors to different substances. The "new" color gradually passes over into the "old." W. L. BADGER

A new and most valuable clarification process for the sugar industry. W. D. STEPHENSON. *Planter and Sugar Mfr.* 74, 353 (1925).—Lime as the sucrate is added to the raw juice in a coagulator. The rate is adjusted to produce the max. pptn. of impurities through the neutralization of the natural acidity. The sirup is held at the

optimum p_{H_2} , and with uniform maintenance the excessive action of lime on glucose is avoided. Large flocs are developed, settle rapidly and the juice is brilliant. Fouling of the heating surfaces is avoided. C. H. CHRISTMAN

The refining qualities of raw sugar as influenced by clarification and boiling methods in the sugar factory. T. B. WAYNE. *Planter and Sugar Mfr.* **75**, 128-9(1925).—Ash in raw sugar is detd. as a matter of routine. No est. can be made of its melassigenic action. Spectrophotometric analyses have shown that sugars of certain colors have superior refining qualities. Uniform crystal size is desired to permit proper affination. Mixed grain in sugars denotes poor purging in the raw-sugar factory, with a greater amt. of impurities in the sirup film. Filtrability of raw sugars is a function of the colloidal matter present and closely correlated to the completeness of the original clarification. C. H. CHRISTMAN

Sugar-refinery mother liquor. E. SAILLARD. *Planter and Sugar Mfr.* **75**, 68-9(1925).—The exhausted molasses from the Ba process was examd. for sucrose. Analyses of the molasses before and after fermentation were made. The Clerget method gave low sucrose results. As reducing sugars were absent in the original molasses, and produced by acid inversion, S. corrects the neutral double polarization by subtracting from the Clerget readings the content of hydrated raffinose, and secures a true sucrose content. C. H. CHRISTMAN

Determination of the density and hardness of refined sugar. K. J. SMOLENSKI. *Gazeta Cukrownicza* **1924**, 19-22; *Centr. Zuckerind.* **33**, 857-8(1925).—A lump of the sugar is weighed, then satd. with a light petroleum oil, and its vol. detd. in a voluminometer filled with the same oil. This gives apparent d ; % pore space can be detd. by weighing with and without the oil. True d_s are about 1.56, pore spaces 13-20%. apparent d . 1.14-1.31. W. L. BADGER

Catalysis in the sugar industry. E. SAILLARD. *Planter and Sugar Mfr.* **74**, 269(1925).—In sirups, oxidation of H_2SO_3 and sulfites is very slow. Pptn. of CaO by H_2SO_3 is retarded in sirups and is not complete after 24 hrs., even when present in equiv. aunts. Pptn. by Na_2CO_3 is not complete but is greater than with the acid. Heat, agitation and kieselguhr accelerate the pptn. Incompleted pptns. such as these have a direct bearing upon the incrustation of evap. surfaces. C. H. CHRISTMAN

The application of high-pressure steam to power generation in the sugar industry. P. LIMPRECHT. *Centr. Zuckerind.* **33**, 739-43, 780-81(1925).—A lecture discussing the generation of steam at pressures up to 1000 lbs., its use in power generation, and its effect on the heat balance of a sugar mill. Pressures over 40 atm (600 lbs.) are not desirable until the demand for heat is larger in proportion to the demand for power than at present. W. L. BADGER

High-efficiency turbines and their effect on boiler pressures in the electrification of sugar factories, especially considering possible changes in evaporation. W. HEUCKE. *Centr. Zuckerind.* **33**, 621-3(1925).—If a general electrification is planned, the turbine of highest efficiency should be selected, and boiler pressures of 300-350 lbs. chosen. This makes possible a change of existing evaporators to pressure evapn. with the min. expense. W. L. BADGER

A contribution to the theory of evaporation with special reference to sugar-factory operation. BOHUMIR PRACEK. *Z. Zuckerind. Cechoslov. Rep.* **49**, 315-21, 323 S(1925); *Listy Cukrovarnické* **43**, 41ff(1924-5); cf. *C. A.* **18**, 3122.—Mathematical. W. L. BADGER

Present methods of preparing thick juice. G. BARTSCH. *Deut. Zuckerind.* **50**, 747-51(1925).—A review, with many references, of recent articles on diffusion, carbonation, filtration and sulfitation. W. L. BADGER

The significance and economy of filtration of thick juice with activated carbon. V. SÁZAVSKÝ. *Z. Zuckerind. Cechoslov. Rep.* **49**, 487-9(1925).—A lecture. The savings are considerable. W. L. BADGER

Raw-juice heating by vapor injection in the Frisia (Holland) sugar factory. KROON. *Centr. Zuckerind.* **33**, 779(1925).—Juice from the measuring tanks is pumped through an ordinary heater operating on vapors from the 4th effect. It is then drawn by vacuum to an elevated jet condenser, where it is heated by vapors from the 3rd effect. From the fall pipe of this condenser it passes to another where it is heated to 94° by vapors from the 2nd effect. It then goes to the carbonation station. The increased evapn. caused by diln. is estd. as 12.6%. Diln. of the juice results in better color and better heat transfer in the evaporators, so additional surface is not needed. The evaporator condenser takes less water. W. L. BADGER

The composition of juices in the campaign of 1924-5. JIRI VONDRAK. *Z. Zuckerind. Cechoslov. Rep.* **49**, 355-62(1925).—The av. figures were detd. from the reports of

23 factories. Diffusion juice: 17.26° Bx., 15.78 polarization, 91.5 purity, 0.10% invert; thick juice: 61.11° Bx., 58.15 polarization, 95.2 purity, 0.042 alky., 0.017 CaO, color 11.2° St. Calcd. to 100 parts sugar, the results for (a) diffusion juice, (b) thick juice and (c) % of material in diffusion juice removed by carbonation, are: Non-sugars, (a) 9.5, (b) 5.1, (c) 46; total N, (a) 0.442, (b) 0.300, (c) 32; albuminoid N, (a) 0.102, (b) 0.002, (c) 98; ammoniacal N, (a) 0.024, (b) 0.003, (c) 92; amido N, (a) 0.034, (b) 0.006, (c) 82; betaine N, (a) 0.124, (b) 0.123, (c) 1.0; harmful N, (a) 0.299, (b) 0.292, (c) 2.0.

W. L. BADGER

The normal juice factor: its possibilities as a basic control factor in the chemical control of cane sugar factories. A. H. WARREN. *Planter and Sugar Mfr.* 74, 369-70, 390-1(1925).—See C. A. 19, 2140.

C. H. CHRISTMAN

Comparative values of normal juice factors. R. ELLIOTT. *Planter and Sugar Mfr.* 74, 449-50(1925).—Data for the calcn. of normal juice factors are shown and it is concluded that, because of different operating conditions, the comparison of factories on the basis of their normal juice factors is useless. Comparable data between factories using flume cane and those which weigh their cane cannot be secured. The Java ratio serves better in this comparison.

C. H. CHRISTMAN

Viscosity tests for sugar solutions. *HAWAIIAN SUGAR PLANTERS' ASSOCIATION. *Sugar* 27, 168-70(1925).—In the refinery all filtered sugars will refilter at the same rate, and original differences in the rate of filtration are due to the insolubles in the original sugars. Sepn. of the insolubles in sugars by passing through linen removes coarse suspended matter. Centrifuging separates out a very fine non-settling matter and the rate of filtration is very closely related to the amt. of this material in a sugar. Poor clarification gives a larger amt. of the material. Liming to the optimum point, with the use of H_3PO_4 in juices deficient in P_2O_5 , improves clarification. Cane wax is a part of the non-settling matter, but not as large a proportion as was indicated in the 1923 report. Optimum clarification produces large vols. of settlings. Oftentimes the lack of adequate filtering and settling capacity requires operation not approximating the optimum. The filtrability of Hawaiian sugars averaged 65.3 in 1922, 72.3 in 1923 and 80.6 in 1924 without increase in polarization, largely because of improved clarification.

C. H. CHRISTMAN

Cause of coloration of juices on evaporation. OTTO PANKRATH. *Centr. Zuckerind.* 33, 619-21(1925).—Criticism minor details of the work of Tschaskalik (C. A. 19, 3333).

W. L. BADGER

The pan station and its steam consumption. ALPH. HEINZE. *Deut. Zuckerind.* 50, 705-8(1925).—The discussion is based on the use of steam at 104-106° from the 2nd or 3d effect of the evaporators during the first stages of boiling, and at 110-115° from the 1st or 2nd effect during the rest of the cook. The effect of the consequent irregular demands on the evaporators is irregular operation, not only in the evaporator station, but all through the mill. It is recommended that for white pans there be not less than 3, of equal size and construction, taking about 9 hrs. per charge, with charges following at regular intervals. Lower-pressure steam should be used in one pan only until the next one comes on. The evaporators must be designed with these fluctuations in mind.

W. L. BADGER

Utilization of ammonia from the ripening of after-product fillmass. EDUARD VIEWEGH AND JAROSLAV HRUDA. *Z. Zuckerind. Cechoslov. Rep.* 49, 331-5, 339-43, 347-53(1925).—Fillmass was ripened in an exptl. crystallizer 900 mm. long, 450 mm. in diam., an exact copy of the Bock crystallizer. The NH_3 evolved was detd. at 12-hr. intervals. The total NH_3 recovered in 144 hrs. in 3 expts., was from 0.0006 to 0.0017 g. per 100 g. fillmass, corresponding to 0.04-0.09% of the total N in the fillmass. W. L. B.

The influence of caramel on the velocity of the crystallization of sucrose. J. A. KUCHARENKO AND Z. B. ROZOVSKY. *Planter and Sugar Mfr.* 75, 130(1925).—The presence of caramel retards the velocity of crystn. of sucrose in proportion to its concn. in solns. of different degrees of supersatn.; equal amts. of caramel exhibit a greater retarding effect in the more concd. solns.

C. H. CHRISTMAN

Petree process at Puunene. W. LOUGHER. *Planter and Sugar Mfr.* 75, 268-9(1925).—Greater recoveries of sucrose were made while the Petree process was operated. The extn. was lower however. Excess bagasse was accumulated because of heat conservation made possible by clean juice. The juice after passing the Peck strainer is limed to distinct alky, to phenolphthalein. Clarified juice is held neutral or slightly acid to phenolphthalein, but alk. to litmus. Kopke centrifugal separators were used on mud. An enlargement of the mud cone on the Dorr clarifier was made to permit greater compression of the settlings.

C. H. CHRISTMAN

The burning of cane to facilitate the harvesting. W. E. CROSS. *Planter and*

Sugar Mfr. 74, 308-10(1925).—Excessive labor costs in harvesting cane have caused many to burn the cane. Burnt cane is subject to rapid deterioration, through loss in juice and in sucrose. The rate of deterioration is affected by the temp. prevailing. After 4 days, cut unburnt cane deteriorated faster than burnt cane, cut or uncut. By zoning off areas sufficient for 1 or 2 days grinding, ill effects from burning are avoided.

C. H. CHRISTMAN

Cane juice p_H measurements. H. A. COOK. *Sugar* 27, 211-2, 264-5(1925).—Detn. of p_H with H electrodes gave results which were considered abnormal. A study of electrodes was made and it is supposed that the error was due to occlusion of protein which even a chromic acid wash would not remove. Freshly platinized electrodes gave consistent results and agreed well with the colorimetric data. Dilm. of the juice 1:9 causes an increase in p_H of 0.3, although this effect is greater q1 the less alk. juices. As a result of this work, it is recommended that not more than 6 detns. be made with an electrode. Detns. should be made on undiluted juice. Electrodes will last longer when the dilm. is 1:3, but the readings will differ 0.1-0.3 p_H from that of the undiluted juices. Directions for removing the Pt coating and replatinizing are given. 60-80 secs. coating with frequent reversals of current are recommended.

C. H. C.

Ash determination by the electrical method in juices and finished products of beet sugar factories. TÖDT. *Deut. Zuckerind.* 50, 745-6(1925); cf. *C. A.* 19, 3040.—This method is far more rapid than and 3 times as accurate as, the usual method. It can be used by non-technical operators.

W. L. BADGER

The influence of air removal on spindle readings on beet press-juice and remarks on methods of analysis for press-juice. FERDINAND KRYZ. *Z. Zuckerind. czechoslovak Rep.* 49, 491-3(1925).—Press juice from beet pulp was kept 25 min. under a vacuum of 700 mm., spindled, and this reading compared with that obtained from fresh juice. A juice of 10.9° Bx. spindled fresh, read 21.6° Bx. after removal of air; one of 20.7° was raised to 22.7° by the same method. Twenty-five samples ranging between these two all came up to 20-22° Bx. by removal of air. Allowing the juice to stand 0.5 hr. in an open flat vessel gave results 1.5-3.6° lower than the vacuum method. The refractometer gave Brix readings on fresh juices checking exactly with readings of the spindle after air removal.

W. L. BADGER

The polarization of molasses. J. J. WEISS. *Z. Zuckerind. czechoslovak. Rep.* 49, 324-2(1925).—A preliminary notice. Ofner's observations (*C. A.* 19, 3029) are confirmed by a careful study of standard samples in different labs.

W. L. BADGER

Further studies on the effect of fine grinding upon starch grains. C. L. ALSBERG AND E. E. PERRY. *Proc. Am. Soc. Biol. Chem.; J. Biol. Chem.* 63, lxvi-lxvii(1925).—"Battered starch grains (ground in a pebble mill) are still birefringent, although they no longer show the black cross under the polarizing microscope. They swell instantaneously when they come into contact with cold H_2O and to a considerable degree disperse themselves in it. They stain instantaneously in H_2O solns. of a number of dye stuffs as well as being dispersed in them. Uninjured starch grains are stained with the greatest difficulty. Solns. prepd. by extg. ground starch with H_2O at room temp. deposit a flocculent ppt. insol. in cold H_2O . However, not all the sol. matter is deposited. The soln. after weeks of standing still contains about 0.5% of a material which colors blue with I. It is pptd. from its solns. by EtOH and the ppt. can be redissolved in cold H_2O if it has not been permitted to become dry."

I. GREENWALD

Liquefaction of starch paste. P. PETIT. *Compt. rend.* 181, 259-60(1925).—To 150 g. of 2% starch paste was added 10 cc. of a soln. contg. NaCl 7 mg., KH_2PO_4 5 and lactic acid 2. The mixt. was shaken for several min. and allowed to stand a few hrs., when a clear mobile liquid without deposit was obtained. The operation was carried out in the presence of toluene to insure sterility of the liquid. The product filters slowly through paper, it is colored blue by I, it does not reduce Fehling soln. and it shows a rotatory power of 195°. Slight variations in the amt. of lactic acid added, retard or even prevent the liquefaction. The most favorable p_H for liquefaction is about 5.0. The slight amt. of silicate dissolved in the liquid seems to favor the liquefaction of the starch paste.

L. W. RIGGS

The salts of Mn, of Al and of I in the fertilization of the sugar beet (COSTA) 15. Changes in sugar content and rate of growth of beets as the result of variations in precipitation (URBAN) 11D. Influence of Al, Mn and Fe salts upon the growth of sugar cane (McGEORGE) 15. K values from residues of molasses fermentation (U. S. pat. 1,555,512) 18.

Utilizing residual waters from pressing beetroot. G. A. DURET. *U. S.* 1,552,737, Sept. 8. Residual waters from pressing beetroot and from juice extn. in sugar manuf.

are evapd. to a sirupy consistency at a temp. of 105–140° to obtain a product which may be used as *stock feed* or as a *fertilizer*.

Apparatus for continuous extraction of sugar from raw materials. A. OLIER.

U. S. 1,555,432, Sept. 29.

Multiple-effect evaporating apparatus for sugar solutions, etc. P. A. BANCEL.

U. S. 1,552,534, Sept. 8.

Multiple-effect evaporating apparatus for sugar solutions, etc. J. F. KIRGAN.

U. S. 1,552,562, Sept. 8.

Starch. P. W. ALLEN. U. S. 1,554,699, Sept. 22. In order to render starch, *e. g.*, corn starch, absorbent and suitable for use in wheat bread it is mixed with H₂O and with an acid such as dil. HCl and the mixt. is heated to effect drying and rupture of the starch cells without effecting, modifying, solubilizing or conversion to dextrin or dextrose.

Glucose. W. B. NEWKIRK. Brit. 232,160, April 11, 1924. See U. S. 1,508,569 (C. A. 18, 3736).

Sugar products resembling malt extract. VERSUCHS- UND LEHRANSTALT FÜR BRAUEREI. Brit. 213,219, March 19, 1923. In prep. products resembling malt ext. by heating sucrose with hydrolyzed albumin, yeast ext. or the like, the reaction is hastened by the addn. of HOAc or other acid, the mixt. being heated to above 80°.

Starch from corn. R. F. SHERMAN. U. S. 1,554,301, Sept. 22. Corn is steeped, disintegrated, the germs are sepd., the starch-bearing material is washed, the resulting starch liquor is returned to the germ separator, then filtered and the filtrate is removed with substantially all the residual sol. substances of the corn. The starch-bearing material is ground and treated with fresh H₂O, starch is sepd. and the resulting residual starch liquor is mixed with the starch from the filtering operation. The liquid obtained from the filtering operation is utilized for the subsequent steeping of grain.

ALLEN ROGERS

Coöperation between tanner and chemist—discussion. F. MOFFAT, *et al.* J. Am. Leather Chem. Assoc. 20, 475–85(1925).—An open discussion at the annual meeting, 1925.

J. A. WILSON

The distribution of tannin in the American chestnut tree with particular reference to stumps and roots. R. W. FREY and L. R. LEINBACH. J. Am. Leather Chem. Assoc. 20, 457–70(1925).—The stumps and roots of the American chestnut, *Castanea dentata*, and of the chestnut oak, *Quercus prinus*, contain about 15% tannin, suggesting their use as a com. source of tannin.

J. A. WILSON

Loss of weight of skins by draining after salting. HENRI VOURLAND. Cuir tech. 14, 356(1925).—Shrinkages up to 12% were observed. Effect of drainage on salt stains is discussed.

H. B. MERRILL

Origin and life cycle of grubs in cattle hides. J. L. WEBB. J. Am. Leather Chem. Assoc. 20, 453–6(1925).

J. A. WILSON

"Synthetic tannin," a useful modern product passing under a pseudonym. RAYMOND DRU. Cuir tech. 14, 348–51(1925).—The term "tannin" should be reserved for materials of vegetable origin. The use of the name "synthetic tannin" for sulfonated phenolic compds. is unfortunate. The admitted usefulness of such compds. in the tannery is not due primarily to their tanning action. Among their useful functions other than tanning are regulation of plumpness of skins, improvement of color, solvent action on insol. matter of vegetable tanning exts. and germicidal action.

H. B. MERRILL

Real and pseudo vegetable tans. C. SCHIAPARELLI AND C. AVENATI-BASSI. J. Soc. Leather Trades Chem. 9, 411–13(1925). (In Italian).—The boiling test of Fahrion may be used to det. the character of vegetable tans. Leather tanned with pure tannin (Kahlbaum) gelatinizes in water at 63–64°; with sumac ext. (Ledoğa), at 76°; with quebracho ext. (Levinstein), at 81–82°. From the industrial viewpoint, pure tannins act as pseudo-tans; this is due to their acidic nature. The tanning action of quebracho is due to its quinone or aldehyde groups, since aldehyde and quinone tannages are stable up to 80–82°. A table of *gelatinization temps. for mineral-tanned leathers* is given.

ROSALIE COBB

The influence of neutral salts on normal violet chrome alum. C. SCHIAPARELLI AND L. CAREGGIO. J. Soc. Leather Trades Chem. 9, 413–18(1925). (In Italian).—Using the *gelatinization temp.* as a criterion of tanning power, S. and C. compare the

action of various chrome salts on hide substance, and study the neutral salt effect. Normal chrome alum yields a product which is more resistant to heat than leather tanned with $\text{Cr}_2(\text{SO}_4)_3$. Addn. of K_2SO_4 to the $\text{Cr}_2(\text{SO}_4)_3$ soln. in amt. sufficient to form chrome alum, does not increase the stability of the leather over that made by the $\text{Cr}_2(\text{SO}_4)_3$ alone. In observing the neutral salt effect the results obtained by Burton and Thomas are not confirmed. Increasing NaCl concn. lowers the temp. of gelatinization from the 85° of chrome alum alone to 75° when NaCl = wt. of skin; time of tan, 18 hrs. Results are tabulated over ranges of several hundred hrs., showing effects of NH_4Cl , FeCl_3 , SnCl_2 and HgCl_2 . ROSALIE COBB

Dependence of reciprocal precipitation of gelatin and colloidal chromic oxide hydrosols on the equivalent aggregation of the chromic oxide micelle. Contribution to the theory of chrome tanning. R. WINTGEN AND H. LÖWENTHAL. *Kolloid-Z.* 34, 289-95(1924); cf. *C. A.* 17, 1743; 18, 1220, 2989, 3509.—At the point of max. pptn., in the mixing of Cr_2O_3 and gelatin sols, the no. of equiv. aggregates of Cr_2O_3 for a given quantity of gelatin is always the same for the same kind of gelatin, no matter what the degree of dispersion of the Cr_2O_3 sol. A value of about 30,000 is thus found for the mol. or equiv. aggregate weight of gelatin, which is in agreement with values found by osmotic measurements (cf. Biltz, *C. A.* 11, 735). Temp. rise, or the addn. of dil. acid or alkali, appears to cause a disintegration of these large aggregates. In technical chrome tanning liquors, ultrafiltration shows the presence of both colloidal and crystalloidal components. By expts. with Cr_2O_3 sols on gelatin leaves, and on solidified gelatin solns., it has been shown that a high degree of dispersity of the chrome sol is necessary for satisfactory tanning. B. C. A.

Contribution to the study of sole leather. CESARE SCHIAPARELLI. *J. Soc. Leather Trades Chem.* 9, 418-26(1925). (In Italian).—The lab. detn. of water-solubles in leather is not made under conditions corresponding to tannery practice. Sol. matter is divided into 4 classes: (A) The material most easily eliminated, sol. at room temp., (B) the substance sol. only above 50° (Procter) (this class gives to leather a certain impermeability), (C) less sol. than B; does not give a tannin reaction, (D) does not give tannin reaction, yet seems to add to the substance of leather. Tables show check detns. for A, B, and C. Successive expts. should be made, first in cold, then in warm water. Some leathers which are low in water-sol matter are high in water-absorbing power and tensile strength. ROSALIE COBB

A device for preparing light leather samples for analysis. R. W. FREY. *J. Am. Leather Chem. Assoc.* 20, 470-5(1925).—A hand-operated device in which the cutting is done by safety razor blades. J. A. WILSON

Provisional method for the determination of sulfates in chrome leather. H. C. REED. *J. Am. Leather Chem. Assoc.* 20, 448-9(1925).—The principle of the Thomas method is employed (cf. *C. A.* 14, 2102). Total sulfate is extd. by means of boiling NaH_2PO_4 soln. and neutral sulfate with water. The acid extd. with the neutral sulfate is detd. by titration with NaOH and deducted. The difference between total and neutral sulfates is recorded as combined acid sulfate. J. A. WILSON

The development of the German glue industry. OSKAR EISMANN. *Farben-Ztg.* 30, 1765-6, 1829-30, 1897-8, 2037, 2101, 2235(1925); cf. *C. A.* 19, 3035. F. A. W.

Electro-ultrafiltration of gelatin and glue (BECHHOLD, ROSENBERG) 2. Hardening gelatin (Brit. pat. 231,564) 18. Molded fiber articles (U. S. pat. 1,552,625) 18.

Destructive distillation of leather waste. J. MICHELMAN. Brit. 231,888, April 3, 1924. Leather waste is destructively distd. in closed chambers at about 600° for 6-12 hrs. and the volatile products are condensed, washed and collected. The C residue is of open porous texture suitable for use in clarification and decolorizing processes. If chrome leather waste is used, the Cr oxide may be recovered by burning the carbonaceous residue in an air current. With tannin-tanned leather scrap, the ammoniacal layer formed is sepd. from oily layers by treatment with CaCl_2 and evapn. of the supernatant liquor, thus obtaining NH_4Cl and hydroxy and carboxylic benzene derivs. or the NH_3 may be recovered as sulfate. Tarry and oily substances are washed with H_2O and pyrrrole, pyrocoll and pyrrrole derivs. remain as a residue.

Tanning. J. R. BLOCKEY AND W. WALKER & SONS, LTD. Brit. 230,879, Oct. 16, 1923. Swelling of hides and skins during tanning is controlled by regulating the pH of the tanning liquor and maintaining it const. during the whole process, by adding neutral salts such as NaCl .

Tanning composition. T. BLACKADDER AND H. C. REED. U. S. 1,555, 782, Sept.

29. A waste sulfite liquor prepn. is made with an acidity, expressed in terms of HOAc, equal to about 15% of the dissolved solids, and with substantially no ash-forming constituents other than CaSO_4 . This liquor may be used in tanning or plumping.

Purifying gelatin and glue. H. BECHHOLD. Brit. 232,077, June 26, 1924. A soln. of gelatin or glue is filtered through an ultrafilter membrane which may be prepd. from a 4% collodion soln. by coagulation with HOAc. The filtration may be repeated and may be facilitated by use of an elec. current.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Latex preserved with sodium hydroxide. O. DE VRIES AND N. BEUMÉE-NIEUWLAND. *Arch. Rubbercult.* 9, 694-713(1925). (In English, *Ibid* 714-20.)—Latex may be preserved indefinitely by the addn. of 7-9 g. NaOH per l., while 6 g. is not always enough to prevent spontaneous coagulation after long keeping. As with latex preserved with NH_3 , the alkyl. of the latex to phenolphthalein remains const. or decreases slowly when it is greater than 0.07 *N* but decreases rapidly when below 0.05 *N*. Crepes from latex which had coagulated after the addn. of small amts. of NaOH vulcanized rapidly. The slope was normal but the tensile strength in some cases was low. The viscosity was at first high but decreased after keeping the rubber 2 yrs., though the rubber did not become tacky in this time. Crepes prepd. with HOAc immediately, 1 day, 1.5, 3.5, and 6 mos. after addn. of NaOH to the latex (5.78 g. per l.) cured in <35, <45, 80, 60, and 50 min. resp. (control 110 min.). The viscosity changed with the time of cure. The variation in time of cure was less marked when the latex was dild. before coagulation. None of these samples became tacky in 2 yrs. Latex preserved with 11 g. NaOH per l. for 2 years sepd. into 3 layers which were coagulated separately. Rubber from the top layer had a low viscosity, was abnormally plastic and cured in 55 min. That from the middle layer had a normal viscosity and plasticity and cured in 30 min. The tensile strength of both these layers was low. The lower layer was abnormally viscous and somewhat plastic. **Latex with larger amounts of sodium hydroxide.** *Ibid* 721-49, 750-60. —A stiff paste contg. 60% rubber formed in 1 or 2 weeks in latex contg. 2% NaOH and in 12 hrs. in latex contg. 5% NaOH. The paste remained in the same condition for a yr. or more and could be dild. with H_2O to a latex-like liquid. Rubber formed by drying the paste became tacky in a few weeks, while that prepd. with HOAc became tacky in a few mos. Dialyzed paste coagulated with EtOH gave a rubber which began to be tacky only after 2 yrs. This tackiness is attributed to a H_2O -sol. substance formed by the NaOH. The N content of crepes from pastes was low and decreased with increasing age of the paste, but the time of cure was about 40 min. regardless of the NaOH concn. and of the age of the paste. The rubber was very weak and plastic.

F. H. YORSTON

Why does latex rubber become tacky even after vulcanization? RUDOLF DITMAR. *Gummi-Ztg.* 39, 2285-6(1925). —A film of rubber obtained by evapn. of latex preserved with NH_3 becomes tacky when exposed to the air in summer, but if maintained artificially at a similar temp. in winter this tackiness does not appear. In the latter case the humidity is lower, and if the film is preserved over CaCl_2 in summer it likewise does not decompose. Furthermore a film obtained by evapn. of a C_6H_6 soln. does not decompose under those conditions most favorable to decompn. of the evapd. latex. This differing behavior of evapd. latex and an evapd. C_6H_6 soln. is due in part to the NH_3 dispersed in the globules (cf. Ditmar, *C. A.* 19, 1792) and in part to the fact that in latex rubber the tackiness is due to decompn. of the protein envelope, whereas in rubber from C_6H_6 soln. the globules have been destroyed and a coating of rubber protects the protein from decompn. This latter assumption is supported by the fact that brief treatment of latex rubber with C_6H_6 renders it far less prone to decompn. Tackiness which always appears in latex rubber vulcanized with S_2Cl_2 is ascribed to the fact that the S_2Cl_2 does not penetrate the protein covering and react with the rubber but is merely absorbed by the protein, where with H_2O it slowly forms HCl and S or with H_2O and air forms H_2SO_4 . The H_2SO_4 renders the vulcanized rubber nuclei tacky. Likewise in the hot vulcanization of an evapd. emulsion of latex with S, true vulcanization of the rubber does not occur, for the S is inhibited by the protein covering from reaching the rubber. By milling the mixt. before vulcanization, however, the protein covering of the globules is broken, S comes in contact with the rubber, true vulcanization results and the vulcanized product does not become tacky.

C. C. DAVIS

The examination of raw materials in the rubber industry. II. PAUL MENSIER. *Rev. gén. caoutchouc* 1925, No. 14, 15-6; cf. *C. A.* 19, 3386.—Suggestions for the examn. of talc, ZnO, lithopone, PbO, MgO, lampblack, Sb sulfide and S are given. C. C. D.

Colloidal litharge in the rubber industry. RUDOLF DITMAR. *Rev. gén. caoutchouc* 1925, No. 14, 3-5.—Colloidal PbO (0.0001-0.00001 mm. diam.) can be dispersed more uniformly in rubber than ordinary PbO (0.01 mm. diam.) and as an accelerator it greatly increases the rate of vulcanization and gives a vulcanized product of superior texture, toughness and durability. Comparative tests with different mixts. are given to illustrate these effects. C. C. DAVIS

Bulk test with *p*-nitrophenol (as a mold preventive). H. P. STEVENS. *Bull. Rubber Growers' Assoc.* 7, 419-20(1925); cf. *C. A.* 19, 2145.—The efficacy of *p*-nitrophenol as a mold preventive was again demonstrated in an expt. with a case of smoked sheet. The results of vulcanization tests on moldy and on treated sheets were similar to previous ones (cf. *C. A.* 19, 749). F. H. YORSTON

2,4-Dinitrophenol (in rubber preparation). H. P. STEVENS. *Bull. Rubber Growers' Assoc.* 7, 359-60(1925).—A satisfactory vulcanizate was prepd. under ordinary conditions from a mixt. contg. 1% of 2,4-dinitrophenol. F. H. YORSTON

The accelerator B. B. A. D. LUTTRINGER. *Caoutchouc & gutta-percha* 22, 12814-7 (1925).—"B.B.," a deriv. of dimethyl-*p*-phenylenediamine, is a brownish black sirup which has a powerful plastifying action on rubber and is an accelerator of wide application. Its accelerating power is increased by ZnO, PbO, MgO, etc. The best results can be obtained with 0.25-0.50% B.B. and 5% S based on the rubber and with ZnO, under which conditions high tensile strength, resilience and resistance to tearing and abrasion and very good aging properties are obtained. With greater amts., vulcanization can be carried out at low temps. or in very short times. Typical formulas contg. B.B. for press, steam and dry heat cures are given, together with a comparison of the oven aging of a mixt. contg. B.B. with the same base mixt. contg. several other accelerators. C. C. DAVIS

Accelerators and their use. L. STOLL. *Rubber Age* 17, 407-10, 418(1925); cf. *C. A.* 19, 2145.—A review of the development of inorg. and org. accelerators and their properties, with a bibliography of 133 references. C. C. DAVIS

The recovery of rubber solvents by highly active carbon according to the Bayer and the Metallbank processes. RUDOLF DITMAR. *Caoutchouc & gutta-percha* 22, 12810-2(1925).—A description, with diagrams, of the recovery of solvents by the Bayer (cf. Berl and Andress, *C. A.* 15, 3194; 16, 450; Carstens, *C. A.* 16, 2374) and the Metallbank processes. The latter differs from the former in that heat losses are minimized by utilizing the counter-current principle. The air contg. the vapors to be recovered passes up through a mass of active C which is slowly descending through a constriction into a lower chamber. The latter is composed of tubes heated externally by gas, through which the satd. C passes and where the vapor is expelled. At the top and the bottom of this recovery system inert gas flows in and after sweeping through the C flows out at the middle section into a condenser where the entrained vapor is recovered. The regenerated C continues downward into a cooling chamber at the bottom and is then returned to the top of the system where it again starts its downward path through the adsorption chamber. C. C. DAVIS

The action of light on rubber. KEIICHIRO ASANO. *India Rubber J.* 70, 307-10 347-52, 389-96(1925).—Expts. were directed toward explaining the nature of the changes in raw rubber induced by radiation of different wave lengths both in inert gases and in air. Sheet rubber and films obtained by evapg. a C_6H_6 soln. *in vacuo* in darkness were exposed at about 40° and in all cases the product was examd. for changes in soly., decrease in viscosity (d-polymerization) and oxidation. The radiation included wave lengths from the infra-red to those shorter than 2000 A. U., as well as sunlight. When rubber was exposed to ultra-violet light in inert gases such as CO_2 , N or H it was converted in part to a white, opaque, brittle, polymerized substance insol. in C_6H_6 and in part to a depolymerized, tacky product, the 2 products having much the same compn. In CO_2 the O content did not increase to a degree indicating that the insol. substance was an oxidation product and control tests of the action of ultra-violet light on CO_2 failed to reveal the formation of CO and O (cf. Bruni, *C. A.* 16, 4093). On exposure to ultra-violet light and air 2 products were again formed, a tacky, transparent mass sol. in C_6H_6 of reduced viscosity (indicating depolymerization) and an opaque, brittle substance sol. in C_6H_6 . Comparison of the action of each part of the spectrum showed that the visible part and the ultra-violet down to about 3100 A. U. passed through the rubber and had no significant effect. Between 3100 and 2250 A. U. a strong fluorescence appeared and below 2250 A. U. the light was completely absorbed. In conformity with

this, the phys. and chem. changes in the rubber were most rapid and profound in the region 2250–2000 A. U., indicating selective absorption of light by rubber. In rubber films dyed various colors with org. dyes the action of the spectrum extended to longer wave lengths than in undyed rubber, and for a given wave length the action was more severe in dyed rubber, indicating a greater absorptive capacity of the colored rubber, with its max. below 2250 A. U. as with uncolored rubber. Only in sunlight where there was almost no radiations below 2910 A. U. did oxidation occur to any considerable extent. Exposure to sunlight caused tackiness, followed by brittleness, the ultimate product being insol. in boiling C_6H_6 , $CHCl_3$, $EtOH$ or Me_2CO , and contg. 14.6% O. The action involved an initial depolymerization, with subsequent accelerated oxidation of the depolymerized product. This oxidation was induced by light of wave lengths below 5000 A. U., while the depolymerization was effected by longer wave lengths. Elimination of the heat effect by filtering the light through H_2O did not alter its effect on the rubber. Under all conditions the intensity of the light governed the rapidity with which the changes were brought about, in conformity with the general laws of photochem. action. As a protection against oxidation induced by light, light with wave lengths below 5000 A. U. should be excluded and rubber may also be protected by a dense layer of dye to reduce the intensity (quantity) of light and thus inhibit depolymerization. In practice this can be accomplished by storing the rubber in red, orange or yellow light. As an aging test for rubber it is recommended that the samples be maintained at 71° in a steady current of air and at the same time be exposed to artificial ultra-violet light until the changes are of sufficient magnitude to compare the stress-strain curves and the chem. compns. A bibliography of 49 references to work on the action of light on rubber is included. C. C. DAVIS

Some problems of the paint and rubber industries. B. D. PORRITT. *J. Oil Colour Chem. Assoc.* 8, 139–58(1925).—A review of the prepn. and compn. of raw rubber, its chem. and phys. properties, vulcanization accelerators, effect of aging vulcanized rubber, etc., and of the analogy between the vulcanization of rubber and the drying of oils. Discussion and references. F. A. WERTZ

Paving compositions having a rubber base (ARNAUD) 20. The adsorption properties and particle size of several lampblacks in organic liquids and in crude mixtures, as well as the effect of these lampblacks on the properties of vulcanized products (LE BLANC, *et al.*) 2. Molded fiber articles (U. S. pat. 1,552,625) 18.

Rubber composition. J. MCGAVACK. U. S. 1,555,131, Sept. 29. A compn. which resembles hard rubber and bakelite is formed from rubber, an aldehyde, a phenol and a halogen, *e. g.*, by treating a rubber soln. in CCl_4 with Cl , $PhOH$ and formaldehyde.

Rubber composition. W. S. GAUNTT. U. S. 1,553,438, Sept. 15. A resilient compn. adapted for making tires comprises rubber gum, zapote gum, ZnO , metallic wool and S.

Rubber compositions. A. JEFFREY and B. WILKINSON. Brit. 232,015, March 18, 1924. An oxide or sulfide of Pb, Sb, Mg or Zn (or mixts. of these) and S are added to latex and the mixt. is coagulated by stirring or agitation alone. The coagulum is removed from the serum and made directly into tiles, mats, boot soles, leather substitutes or other articles.

Rubber compositions. R. RUSSELL and H. BROOMFIELD. Brit. 231,988, Feb. 26, 1924. A spongy, non-adhesive compn. suitable for use in rubber mixts. is prepd. by mixing heated latex with a heated aq. soln. of glue, gelatin, etc., and adding a coagulant for the latex and a hardener for the glue. NH_3 and formaldehyde may be used and oils, treacle and fillers may be added.

Colored rubber articles. W. G. MARTIN and NORTH BRITISH RUBBER CO., LTD. Brit. 232,421, May 12, 1924. Colored rubber articles assembled from pieces of vulcanizable sheet rubber and vulcanized by the dry heat process are made from sheet contg. piperidine pentamethylenedithiocarbamate or other accelerator of similar type.

Crude rubber from latex. R. HOPKINSON. U. S. 1,550,319, Aug. 18. Latex is desiccated to obtain all of its solid constituents and these are heated to produce a mass of dark color throughout, adapted for working and vulcanizing.

Molds for rubber. G. HAKANSON. U. S. 1,550,160, Aug. 18. In prepg. molds of vulcanized rubber for articles of soft rubber with a surface decoration in resemblance to textile fabric, a textile pattern is impressed on the non-vulcanized mold material and the latter is vulcanized with the pattern in place. The pattern is destroyed after vulcanization.

Rubber repair patch. H. H. THEIS. U. S. 1,553,883, Sept. 15. Gum rubber is applied to one side of a layer of cured rubber and the outer face of the gum rubber is treated with a skim coat comprising benzine 2 and "cold patch cement" 1 part. This is covered with a protecting fabric sheet impregnated with starch.

Vulcanizing rubber. E. ROMANI. U. S. 1,555,256, Sept. 29. Zn α -phenylbi-guanide is used as a vulcanization accelerator.

Vulcanizing rubber. S. M. CADWELL. U. S. 1,552,820, Sept. 8. Rubber is mixed with S, Pb dithiobenzoate and Pb oxide, and then vulcanized.

Masticating rubber. H. C. YOUNG and C. MACBETH. U. S. 1,556,141, Oct. 6. Mech. features.

Bearings of rubber. C. W. JOHNSON. U. S. 1,555,214, Sept. 29. Bearings for shafts of automobile steering column, etc., are formed with a backing of soft rubber integrally united with a hard rubber bearing facing contg. a small proportion of a lubricant such as graphite.

CHEMICAL ABSTRACTS

No. 23

I. AUTHOR INDEX

("P" before a page number indicates "Patent")

NOTE.—In the transliteration of names originally written in Russian, the system followed so far as possible is that of *Nature* (Feb. 27, 1890), in which *v* is used instead of the *w* or *ff* of other spellings, *sh* instead of *sch*, *ch* instead of *tsh*, *i* instead of *j* or *y*, etc. Thus Pavlov, not Pawlow; Chugaev, not Tschugaev. To make quite sure, users of the index should in such a case look under both spellings.
